30725. Bird Line section renovation

Yahoo group: ham-antennas (2014)
Date: 2014-01-01 03:54:05 UTC
From: Martin A Flynn
Topic: 30725 Message: 30725

I picked up a Bird 4600-000 line section to pair with a 3KW dummy load. It apparently lived in a field due to the mud in the crevices.

Collateral damage from the mud was minimal, other then the set screws holding the center section are rusted. I soaked them in CFP for a few days, with 4 of the six coming out with no damage. The last two stripped.

Other then drilling and an easy out, anyone have a magic cure to extract them?

If by "stripped," you mean stripped the threads, then you might as well drill them out and thread the holes for a larger screw.

If you mean the head of the screws deformed so a screwdriver no longer grips it, you might try a screw extractor. Maybe that's what you mean by an "easy out." Liquid Wrench might help.

Nothing magic but from an old tool and die maker in a research lab, the best penetrating oil is made be Kano, Kroil Oil (the oil that creeps)

http://www.kanolabs.com/

I would let it soak in before I tried anything. You can get it at Amazon , E-Bay, auto supply stores, many places.

Try COKE not diet on the threads or WD40.

My xyl uncle woored under ground in amine and he told us if either of these fluids dont work then drilling is only option.

if you have to resort to drilling try to find a bit with a left hand twist , if it jams in whatever is being drilled it will unscrew it instead of running it in tighter if it breaks loose .

30730. RE: [ham-antennas] Re: Bird Line section renovation

Yahoo group: ham-antennas (2014)
Date: 2014-01-01 15:54:37 UTC
From: Richard Schmuke
Topic: 30725 Message: 30730

Left hand drill bits do work, I have used them on round head steel drive screws that are made not to be removed. You need the penetrating oil to loosen the screw first and finding the correct size left handed drill bit is difficult outside of a well stocked machine shop. If you find a place to buy a left hand bit be sure it is a real left hand rotation bit and not just left hand twist. They make common cutters that are right hand cut but with a left hand twist to the flutes to prevent grabbing. You want left hand cut.

Rich, kd0zz

if you have to resort to drilling try to find a bit with a left hand twist , if it jams in whatever is being drilled it will unscrew it instead of running it in tighter if it breaks loose .

Easy-Out is the trade name for a left-handed-twist broken-screw or stud extractor. One must drill a hole into the broken screw, then by inserting this device into the hole, one can back the broken...whatever...out.....iff you don't break the Easy-Out off inside the broken screw.

Since the Easy-Out is made of VERY hard steel, if you break one off, about the only recourse is an acetylene torch. Not pleasant.

The Easy-Out was first made available for auto-mechanics to remove broken studs from engines.

They come in various sizes.

To my way of thinking and in my experience, they are a measure of last resort.

Snap-On - or was it MAC, came out with a stud extractor set that worked fairly well..you drilled a hole through the broken stud/screw, etc., and then with a soft hammer, pounded this steel 'rod' through the hole..the 'rod' had 'edges' that extended down 4 sides of the 'rod'. After it was in the stud/screw, etc., to be extracted, you slid a 'nut', that was made to slide down the 'rod', and using a correct sized open or box wrench, unscrewed the broken stud. Like the tapered Easy-Outs, the 'rod' was cold rolled steel, and it often broke, but at least with it, you could drive it through the hole.

One of the misguided assumptions is that you can actually get a hole drilled through the offending bolt. 99% of the time the drill will wander out the side of the bolt and the screw extractor is futilely working on the surrounding metal.

Bruce,
In this case, I am lucky that there is an adjoining hole I can thread another bolt into to make sure the drill is going to stay where it's supposed to be, IE use the second bolt to confirm the failed Allen screw is aligned vertically on the drill press bed.

Bruce...

Most professional mechanics I know, that, years ago, included me, (Now I am no more than a shade tree'er) learned, over the years, how to drill a straight and narrow hole. (The trick was to file the protruding stud flat to the surface, then, carefully center punching a drill start, concave the surface of the broken stud/bolt with a drill bit that was the size of the broken stud/bolt, then center punch it again, and drill the hole, using the appropriate sized drill bit.)

However, if one were to drill off-center and into the 'wall' threads, the offending bolt/stud, etc., was easy to get out. at that point!

I've used that method dozens of times. Simple fact most old bolts are not consistent in internal density. Unless you can get the part on a bench with a quality drill press, 99% will go astray. That has been my experience for close to 50 years now since my father handed me a drill,bit and an Easy-Out.

30737. File - rules2.txt

Yahoo group: ham-antennas (2014)
Date: 2014-01-02 03:08:52 UTC
From: ham-antennas@yahoogroups.com
Topic: 12267 Message: 30737

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

Nice loop. I'm a fan of loops to be honest. I have made plenty of loops with 4:1 baluns for multiband use. I made a 2:1 balun for a monoband for the match which worked very well. The ladder line works well but I prefer a match to the 50 ohm coax.

Loops are great antennas. The only downside is the requirerment for some space and good supports. You will be very happy with your loop, Dean, and you will work lots of DX especially on the higher bands. happy new year by the way!

Hi dave,

It's constructed like this

http://27mhzww.fortunecity.ws/baluns.html

Toroid is the ft-140 43 but I think maybe the ft-140-61 would be a better choice.

The 43 material is the better choice for HF (1-50MHz) ...61 is
generally used more for VHF (10 Mhz -200MHz)

Topic: 30741 Message: 30749

Billy,

First check your dummy load resistor. You need to have NON INDUCTIVE resistor. Connect 200 Ohm resistor direct to your Antenna Analyzer. The SWR readings must be FLAT (near 4:1) in wide frequency range. If not - you have inductive resistor and need to replace him to have correct readings. You can use few metal / carbon resistors connected in series or parallel to get necessary value.

I have a build in last year a number of 1:1, 4:1 and 9:1 baluns similar to your's and never had big problems.

Regards,
Andy - YL2QN

From: Thomas W4HM
Topic: 30738 Message: 30751

I also use an 80 meter full wave loop at this location in central Florida. It's actually a bit longer at 300 feet with each leg at 75 feet long. It's supported at each corner by oak trees and up at 35 feet. It's fed with 41 feet of 300 ohm window line to an MFJ-974HD balanced antenna tuner.

It's pretty much and NVIS antenna on 80 and 60 meters, a good DX antenna on 40 meters and and outstanding DX antenna on 30-6 meters. I also use the antenna for SWL DXing and programming listening.

I have a web page on the antenna also at
http://www.wcflunatall.com/w4hm15.htm .

Dave / kd6il

I am curious have you ever run a swept frequency response curve on the
MFJ unit (like the previous poster) using a 200 ohm resistor and an
antenna analyzer???

Hi Thomas,

That is the MAIN antenna that I tried to pattern mine after!! The drawing is almost exactly like the configuration of my antenna, feedpoint and all! I had already saved that file in my computer many weeks ago. My antenna is about 36 feet high at each corner, and I'm using about 100 feet of 450 ohm ladder line. I just my SGC MAC 200 automatic tuner today and installed it! It tuned up all bands 80m - 10m in just a few seconds except 30m. Would not tune 30m better than about 3.5:1, but that band is least important to me.

Thanks!

Hi Ken,

Sorry for the delay in replying. With your links and some other info, I now have so much data that I am even more in the dark. I have reached several conclusions.
1 Using a stripped back coax cable is a goer.
2 It will probably need to be double independent screened cable.
3 The matching is going to be tricky.
4 The first RF Amp would best be at the Antenna feed.

I'l come back in a short while to report progress.

If anybody has further thoughts or relevant links I would be grateful for the info.

Thank you all for your input.

Ray

Hi All

Happy New Year
Last week I was in the yard stringing out wire for a vertical delta loop.
Started talking to a friend a cross the street.I measured out about 67 feet per side.
I hooked up the Balun put it up in the tree about 80 feet at top and about 20 feet off the ground.
I wanted an antenna for 80 meters for jt 65.
After I put it up and was getting good results into EU from Louisiana, I realized I had made my measurements wrong.That what I get for not watching what I was doing.Hi Hi.
But the thing is it is working very well on 40 and 80 meters for DX.So now I am thinking should I leave it as it is, are add the extra wire. It is feed with coax I was planning on using ladderline but it go dark and I wanted to just try it out.
Any thoughts

Looking for suggestions. I have an 160 vertical (commercial), and a 6-btv, but as most of you know the 80 meter resonator could better used as a coat hanger.
I would like to erect some type of 80 meter antenna that did not need ground radials as the 160 and the trap radials already cross all over this city lot, and the mower guy hates them. I have a tree and tower that it could be stretched from, but still another thing the mower has to mow around (coax drop) Can't find anything in arrl wire, and vertical books.
Any ideas?

Are there any certain coax lenghts to avoid on a ground mounted 160 vertical that is loaded at the top? Currently running 100', but sometimes feel like I am tuning coax only.
TIA

Well Dale if you read the literature you will know that an antenna
without ground radials.
Check out this page at the bottom for the literature on that subject.
http://www.bencher.com/pdf_download.html
W0DN(SK) (Butternut founder) did a couple of papers on the subject of no
ground radials also.

But for your query have nothing to help with because I don't recall
seeing anything in the ARRL handbook or Antenna book.

How tall is the tower
How tall is the tree
How far apart are they

The Length of radials which are laying on the ground are not
particularly critical as to length (elevated radials can be critical)

More accurately a SHORT(1/4 wave) GROUND MOUNTED VERTICAL with out
radials is inefficient . A vertical 1/2 wave dipole is just fine (but
not practical for 80M) without radials as an example

From: <w6jhb@...>
Topic: 30766 Message: 30773

Dale - I live in a city on a small lot and have an 80 meter Inverted L. It uses NO radial but has a K2AV folded counterpoise - FCP. It works very well. The vertical part runs 40 feet up the side of a tree and the horizontal part runs over to the house, sloping down. Fed with 110 feet of 50 ohm coax. Jim / W6JHB

30774. Re: antenna woes

The only thing that comes to mind is the Hy Gain patriot line (pricey) or maybe Gap Titan (also pricey).

Hy gain has a better following.

Also a end fed with 1 counterpoise. May require a remote tuner.

I would like to erect some type of 80 meter antenna that did not need ground radials as the 160 and the trap radials already cross all over this city lot, and the mower guy hates them. I have a tree and tower that it could be stretched from, but still another thing the mower has to mow around (coax drop) Can't find anything in arrl wire, and vertical books.
Any ideas?

Are there any certain coax lenghts to avoid on a ground mounted 160 vertical that is loaded at the top? Currently running 100', but sometimes feel like I am tuning coax only.
TIA
Dale K8TS

Well Dale if you read the literature you will know that an antenna without ground radials.

Sorry didn't finish my thought
An antenna without ground radials is inefficient.

Check out this page at the bottom for the literature on that subject.
http://www.bencher.com/pdf_download.html
W0DN(SK) (Butternut founder) did a couple of papers on the subject of no ground radials also.

But for your query have nothing to help with because I don't recall seeing anything in the ARRL handbook or Antenna book.

how about an trapped inverted l for 80 and 160 .trap is made from rg58
and you exsisting ground radials will do just fine

http://www.users.icscotland.net/~len.paget/6_band_inverted_l_antenna.htm

I used 1 for a few years and liked it alot

30777. Affect of Ice on Beam, Dipoles, Multiband Vertical Antennas

Yahoo group: ham-antennas (2014)
Date: 2014-01-05 14:38:41 UTC
From: <myfamilydotcom@...>
Topic: 30777 Message: 30777

We have had a severe ice build-up on everything outside for a few weeks straight, and unfortunately the temperature has remained below freezing and the ice has stayed.

I operate a TA-33 M-WARC beam, a Cushcraft multiband vertical, and several diploes. They are totally covered with at least 1/4" of ice everywhere, and in some places it's 1/2 ".

My dipoles and beam elements are sagging under the weight, but seem to have survived.

While trying to operate over thye holidays, my antenna tuner in my Kenwood TS-570 found a match, but reception seemed quieter than usual and when I spoke (SSB) the SWR meter jumped erratically on voice peaks. I presume that the ice has altered the elements' characteriatically substantially, and so too the beam traps; perhaps the ice is breaking down on power peaks etc.

Is the SWR jumping something others have seen as well?

FWIW I see this on the dipoles and beam both - not sure about the ground mounted vertical since it has 2 feet of snow above its base.

I also have a TA-33JR. We have had lots of ice and snow as well. Though I have been lucky and the ice does melt off after the storms have cleared. During the time they are iced up I get the same reaction. Swr is notably higher.I have the beam and an OCF Windom dipole. Since our weather has turned bad my dipole actually seems to work better than the beam. Go figure.

it's a bit more trouble . bury 3/4" pvc and run the coax through it , don't forget to put a 180 degree u bend where it comes out of the ground at the antenna base and where it goes into the ground at the house if it is not protected from water getting in it . do not cement the u bend to the pipe,it is easier to remove the bend to get the coax in the longer run . I have an arrangement like that to get the coax out of the basement with 2.5 " pvc . will make it easier if you have to replace the coax .

I do something similar, I come out the ground with 3" into a right angle LB box into the house. That leaves only one 90 for access.

30782. New 80m half sloper salvage antenna test request

Yahoo group: ham-antennas (2014)
Date: 2014-01-05 19:07:28 UTC
From: <ag6az@...>
Topic: 30782 Message: 30782

I put up an 80m homebrew / salvage half sloper using one of the loading coils from a MFJ 80/40 dipole that snapped earlier this year. I used about 44' of new 14 gauge stranded insulated wire with the MFJ coil and the provided 14 gauge non insulated wire. My configuration is that the coil is at the end closest to the ground and the wire extends up to about 40' and attaches to a 1:1 balun and the other wire from the balun attaches to the tower with a stainless hose clamp. It took a little trial and error but I got it tuned at 3.725 at 1.5:1 to 3..810 at 2:1.

I plan to test it tonight and depending on how it works I will use the second coil for another 80m sloper towards JA and Asia. Been fun reusing broken stuff and making antennas out of them.

I will be on 3.803 MHz LSB tonight testing and doing A/B testing against my alpha delta dxcc antenna if anyone wants to give me a report. Hope it works good but still fun to experiment.

Thanks & 73,

Keith

Mel,

Thanks. I will be on at 02:00 UTC for awhile. I have the antenna towards 40 degrees northeast. My plan was to point it towards Europe. I can't wait to see how it works now that it is fully installed.

30785. Antenna Work

Yahoo group: ham-antennas (2014)
Date: 2014-01-05 20:27:08 UTC
From: Richard Schmuke
Topic: 30785 Message: 30785

The forecast for my area is for 12 below tonight and not above zero tomorrow. I have about 8 inches of snow, high wind and a little more coming.

I just wanted to remind everyone that any antenna work done under these conditions will need a frequency adjustment made because of the compression of the atoms in the antenna material and things will get longer when it warms back up.

The above post can be fictional, hypothetical, or downright nonsensical.

Rich, Kd0zz

30786. Re: [ham-antennas] Antenna Work

My elmer taught me from day ONE...work on antennas in nice
weather..nothing will go right! 37+ years as a ham
has proven this to be true. Maybe it's because it was so damn cold, I did
it right-the first time!
Thanks for the "insight" Rich. A long time ago we had an electrician
apprentice believing that you could NOT twist wires together, as it created a
resistive "bump" in the wire. (We also had non-electronic types believing
that getting close to the radar director would make you sterile.)

I don't need to be examined, in fact Waylon Jennings wrote a song about me 25 years ago, when my hair was dark and we looked about the same. Title is " I've always been crazy, but it kept me from going insane". You can hear it on YouTube.

I did wait until the RTTY contest was about over and went out and cleared a path down the drive way, it is about 300ft long and the snow was up to 12". It was down to about 8 degrees but the HYD oil flows better at 8 above now than at minus 12 tomorrow. With the wind today I think I have a broken 450 ohm line but that will have to wait, and yes it has a twist or two in it.

Rich, Kd0zz

Prior to making any adjustments , I recommend having your head examined .

Hi Dale...

Mods for the xBTV series antenna.....

You didn't mention your lot size or available supports, so this may not help. It would most certainly increase your antenna's efficiency on 80m, besides adding 160m.

http://www.hamuniverse.com/k8kas160104btvmultibandantenna.html

The article calls for commercial traps. They are high Q devices and will give you maximum wire length, if your lot can support them. You could make the traps from coax; the 80m wire would be just about the same length, but the 160 wire section would shorten by 10 or 12 feet. I would think bending the antenna wires would be OK to accommodate the lot size.

You can drop Reyco an email and get the current costs on the traps; they will sell one for each band even though the web page seems to show prices for dipole pairs. Mine were about $55 a couple of years ago. Since your only running 100w, you could make your own out of pvc and rg58 coax, or ask someone from your local club.

If your current 160m antenna is working Ok, then just add the section for 80m to increase the radiation efficiency and add some horizontal polarization.

The k8kas mod started out at eham.net, so you might find more info there.

30796. Re: [ham-antennas] New 80m half sloper salvage antenna test request

Yahoo group: ham-antennas (2014)
Date: 2014-01-06 20:15:52 UTC
From: Keith Heimbold
Topic: 30782 Message: 30796

Thanks Mark. I think it is interesting to note that the antenna did seem to have a beneficial directional transmit ability to the northeast, based on a few reports from a little less than 1 S unit to more than 1 S unit at the same power level.

For already strong signals in that direction I saw a corresponding increase in received signals along with an increase in noise level between 1/2 to 1 S unit. For "weaker signals" like those coming from Europe last night like DF2BO and a few others from the UK last night on 3.7999 MHz the dipole's lower noise level allowed me to actually have full Q5 readability while the sloper I could barely copy the signal through the increased noise. I knew they were there but it was more challenging to understand what was being said.

Of course one evenings results doesn't conclude the analysis. I will continue my plan to build another reduced sloper for Asia Pacific direction or 120 degrees offset from the other sloper.

Since you are looking for assistance, I am glad to help. While we can do a quick estimate with little data, it is much more rewarding if we have more data than we can use, hi.

OK, and to give you a little insight as to what is important here is a list of things that matter:

Frequency or frequencies you want to operate
Will you be using a antenna tuner to get the match
How will the antenna be configured, that is center fed, end fed and with what kind of feedline and if possible how long it will be
    That is, horizontal dipole, inverted V, etc.
How high above ground will it be
What if any buildings/structures will be near by, and will the antenna be in a congested area, near water, trees, etc.
What size wire will be used and how will the antenna be supported and where, ends, center and ends
Finally the modelling will be only as good/accurate as the data provided.

That should get us off to a good start. Mostly this is all a great deal of fun for a old retired engineer.

I know here I use an OCF Windom in an inverted V configuration. Its up about 35ft. That's what I was using to QSO with you last night. I also have a Mosley TA-33 jr with the Warc bands. Lately I have found myself using the Windom more often as the Mosley is getting a lot of noise that the wire does not. So as to what your saying I can understand. The Windom does not have "ears" like the Mosley but with less noise I can actually hear more. We are under snow and ice right now but when spring gets here I am going to look into what all the noise is about. Think there might be a noisy power pole transformer to the Northeast of my property..And of course NE is where I want it pointed for European DX. Go figure.

Keith, I must apologize for the critical audio comment on your test. First off, I had the cans on my bad ear, the one with the previously reputered ear drum. And as a result I cranked up the audio level to hear "better" that is why now the audio has distortion on my end. Hate that when it happens.

Anyway, I hope the tests were to your liking. It is always a good feeling when it works as planned. Cheers,

Mel, K6KBE

I know here I use an OCF Windom in an inverted V configuration. Its up about 35ft. That's what I was using to QSO with you last night. I also have a Mosley TA-33 jr with the Warc bands. Lately I have found myself using the Windom more often as the Mosley is getting a lot of noise that the wire does not. So as to what your saying I can understand. The Windom does not have "ears" like the Mosley but with less noise I can actually hear more. We are under snow and ice right now but when spring gets here I am going to look into what all the noise is about. Think there might be a noisy power pole transformer to the Northeast of my property..And of course NE is where I want it pointed for European DX. Go figure.

30802. RE: AW: [ham-antennas] Antenna modelling help!

Yahoo group: ham-antennas (2014)
Date: 2014-01-07 16:24:37 UTC
From: Billy McFarland
Topic: 30785 Message: 30802

Hi Sigi ,

I do make a lot if homebrew things, cables, baluns, ptt adapters, and antennas mainly dipoles, windings cobwebb and now I'm making an optibeam ob6-3m. I don't have any of the modelling software and just now I don't really have time to get it and learn how to use it. I'm building my own house extension. Studying for a promotion exam at work, got two kids under three, tutor at my local radio club and I work shifts to add to the pressure lol. Also I help people design QSL cards and I've got a few to tidy up. Lol

But that's just one dats schedule ;)

Hi Mel,

No worries. I really appreciate you taking time to provide signal reports and enjoyed meeting you on the band.

It was good to have multiple folks on even though it overwhelmed me with so many kind ham operators coming to help me test this antenna.

I have occluded after a couple days that the sloper transmits fairly well in northeast direction but doesn't hear well. I decided to build a single loop temporary K9AY antenna that I have in my mind. It should take no time to put together as I have all the parts for a beverage antenna and for a simple K9AY used similar parts. I will keep everyone updated on how this experiment goes and post photos to the yahoo group.

Thanks & 73,

Keith

30805. Electromagnetic Waves two components which are best

Yahoo group: ham-antennas (2014)
Date: 2014-01-08 00:33:05 UTC
From: <danyoder.cs@...>
Topic: 30805 Message: 30805

Hi All,

I would like to make a few statements below please correct if needed and answer the question if it is of interest to you. The paragraph below my name was copied and pasted from an article that a forum member gave me called Practle Circuits attached.

The rf signal has two components an electric field and a magnetic field. I assume that the modulated AM signal shows up on both components in phase.
Now if you see below an AM radio that has a teleoscopic rod or a long wire antenna responds to the electric field and one that has a loop antenna or ferrite rod coil it responds to the magnetic field. Okay this is cool info, but here is my real concern. A magnetic loop antenna that you would move close to your radio inductivley coupling to the ferrite rod strengthens the signal I assume that they are enhancing the rf voltage or the loop was just tuning out noise and interference. Here is the question, If you have a long wire that is responding to the electric field and a magnetic loop or ferrite rod can both of these two different components electric and magnetic combine and move on to the detector for rectification? Or should you just work with one field at a time. Is one better than the other to harness and filter.
Thanks Dan

Receiving aerials respond to either the electric or the magnetic field
radiated by the transmitter. Sets that use telescopic rod or wire aerials
pick up the electric field. Receivers that have loop aerials, i.e., a coil
wound on a frame or a ferrite rod, respond to the magnetic field.
Portable receivers usually incorporate both: long and medium
waves (150kHz to 1·6MHz) are covered by a loop with a ferrite
rod core, and the v.h.f. f.m. band (88MHz to 108MHz) and shortwave
bands by a telescopic aerial.

Hi Mel

Sorry I missed the email for data. What exactly do you need.

It's fed with 59 ohm coax to a 4:1 balun as on the drawing. Then base of the antenna is 6 inches of the ground and the end of the radiator part is 1m above ground.

Here is a repeat plus I asked if you have any measurements of the antenna SWR without a tuner? Some of the questions you answered.

Frequency or frequencies you want to operate
Will you be using a antenna tuner to get the match
How
will the antenna be configured, that is center fed, end fed and with
what kind of feedline and if possible how long it will be
    That is, horizontal dipole, inverted V, etc.
How high above ground will it be
What if any buildings/structures will be near by, and will the antenna be in a congested area, near water, trees, etc.
What size wire
will be used and how will the antenna be supported and where, ends, center and ends
Finally the modelling will be only as good/accurate as the data provided.

Mel, K6KBE

It's fed with 59 ohm coax to a 4:1 balun as on the drawing. Then base of the antenna is 6 inches of the ground and the end of the radiator part is 1m above ground.

Hi Sigi ,

I do make a lot if homebrew things, cables, baluns, ptt adapters, and antennas mainly dipoles, windings cobwebb and now I'm making an optibeam ob6-3m. I don't have any of the modelling software and just now I don't really have time to get it and learn how to use it. I'm building my own house extension. Studying for a promotion exam at work, got two kids under three, tutor at my local radio club and I work shifts to add to the pressure lol. Also I help people design QSL cards and I've got a few to tidy up. Lol

But that's just one dats schedule ;)

What about lending you a hand and show you how to USE a modelling software and do it on your own ... you have 2 things in one ... modelled your own antenna ... and learned HOW to do that ...

Yes that maybe would take some time (depending on what setup you have /plan to build)

But I guess it would be "more fun"

Do you homebrew things?? Why not learn how to "homebrew" antennas??

Dg9bfc

Sigi

ps mmana is freeware and easy to use ... with LOTS of ready to use models in it.....

30810. Re: AW: [ham-antennas] Antenna modelling help!

Yahoo group: ham-antennas (2014)
Date: 2014-01-08 16:06:33 UTC
From: Billy McFarland
Topic: 30785 Message: 30810

Hi Mel,

oK Here goes:

1.Frequency 7mhz - 30 mhz (it may work on 60m)
2.yes tuner will be used
3.antenna is fed with 4:1 balun at point indicated on drawing. the two 1/4 wave matching sections are shorted together at the very bottom and then from that point its fed 1.05m (this was a guess to where the feed point would be around 200 ohms) the 1/4 wave matching section is vertical with the antenna being just 6 inches from the ground. Once the 1/4 wave sections are vertical (around 10m tall) then it will slope to one side. The end of this radiator will be around 1m from the ground.
4. I will use this antenna as a field day operation so it nothing will be close by as the center will be supported by a 12m mast. On a grass surface. (a field for example).
5. I will be using 10m of 50 ohm coax to the balun.
6. The swr reading I got on 7.15 mhz was around 2:1 the antenna was installed in an inverted V configuration and the centre was supported by scaffolding which is at my house so the swr could be effected by that scaffolding pole.

thanks

On Wednesday, 8 January 2014, 15:28, Mel Farrer <farrerfolks@...> wrote:

Here is a repeat plus I asked if you have any measurements of the antenna SWR without a tuner? Some of the questions you answered.

Frequency or frequencies you want to operate
Will you be using a antenna tuner to get the match
How
will the antenna be configured, that is center fed, end fed and with
what kind of feedline and if possible how long it will be
    That is, horizontal dipole, inverted V, etc.
How high above ground will it be
What if any buildings/structures will be near by, and will the antenna be in a congested area, near water, trees, etc.
What size wire
will be used and how will the antenna be supported and where, ends, center and ends
Finally the modelling will be only as good/accurate as the data provided.

Mel, K6KBE

Alright. The fact that you have a 2:1 SWR on 40 meters is a good sign that the speaker wire is working for you.

I have attached the file to my antenna folder for you.

Mel, K6KBE

30813. Re: AW: [ham-antennas] Antenna modelling help!

Yahoo group: ham-antennas (2014)
Date: 2014-01-08 17:50:49 UTC
From: Mel Farrer
Topic: 30785 Message: 30813

Well, I don't favor a end fed resonant antenna for multi band use. I favor OCF. The match seems to be better, however, as the old saying goes if it ain't broke, don't fix it, hi. Since you seem to have a reasonable match with the tuner. I would stay with it. If however, you run into matching problems, I would have a meter or two handy to add to the bottom of your speaker feed line. Good luck and happy DX'ing.

Mel, K6KBE

On Wednesday, January 8, 2014 9:19 AM, Billy McFarland <gm0obx@yahoo.co.uk> wrote:

Hi Mel,

Got the file. THANKS! it certainly looks the part and should be good for a Field day. What changes if any would you make?

73 de GMØOBX Billy

On Wednesday, 8 January 2014, 16:44, Mel Farrer <farrerfolks@...> wrote:

Alright. The fact that you have a 2:1 SWR on 40 meters is a good sign that the speaker wire is working for you.

I have attached the file to my antenna folder for you.

Mel, K6KBE

On Wednesday, January 8, 2014 8:06 AM, Billy McFarland <gm0obx@...> wrote:

Hi Mel,

oK Here goes:

1.Frequency 7mhz - 30 mhz (it may work on 60m)
2.yes tuner will be used
3.antenna is fed with 4:1 balun at point indicated on drawing. the two 1/4 wave matching sections are shorted together at the very bottom and then from that point its fed 1.05m (this was a guess to where the feed point would be around 200 ohms) the 1/4 wave matching section is vertical with the antenna being just 6 inches from the ground. Once the 1/4 wave sections are vertical (around 10m tall) then it will slope to one side. The end of this radiator will be around 1m from the ground.
4. I will use this antenna as a field day operation so it nothing will be close by as the center will be supported by a 12m mast. On a grass surface. (a field for example).
5. I will be using 10m of 50 ohm coax to the balun.
6. The swr reading I got on 7.15 mhz was around 2:1 the antenna was installed in an inverted V configuration and the centre was supported by scaffolding which is at my house so the swr could be effected by that scaffolding pole.

thanks

On Wednesday, 8 January 2014, 15:28, Mel Farrer <farrerfolks@...> wrote:

Here is a repeat plus I asked if you have any measurements of the antenna SWR without a tuner? Some of the questions you answered.

Frequency or frequencies you want to operate
Will you be using a antenna tuner to get the match
How
will the antenna be configured, that is center fed, end fed and with
what kind of feedline and if possible how long it will be
    That is, horizontal dipole, inverted V, etc.
How high above ground will it be
What if any buildings/structures will be near by, and will the antenna be in a congested area, near water, trees, etc.
What size wire
will be used and how will the antenna be supported and where, ends, center and ends
Finally the modelling will be only as good/accurate as the data provided.

Mel, K6KBE

On Wednesday, January 8, 2014 7:13 AM, Billy McFarland <gm0obx@...> wrote:

Hi Mel

Sorry I missed the email for data. What exactly do you need.

It's fed with 59 ohm coax to a 4:1 balun as on the drawing. Then base of the antenna is 6 inches of the ground and the end of the radiator part is 1m above ground.

Hi Sigi ,

I do make a lot if homebrew things, cables, baluns, ptt adapters, and antennas mainly dipoles, windings cobwebb and now I'm making an optibeam ob6-3m. I don't have any of the modelling software and just now I don't really have time to get it and learn how to use it. I'm building my own house extension. Studying for a promotion exam at work, got two kids under three, tutor at my local radio club and I work shifts to add to the pressure lol. Also I help people design QSL cards and I've got a few to tidy up. Lol

But that's just one dats schedule ;)

What about lending you a hand and show you how to USE a modelling software and do it on your own ... you have 2 things in one ... modelled your own antenna ... and learned HOW to do that ...

Yes that maybe would take some time (depending on what setup you have /plan to build)

But I guess it would be "more fun"

Do you homebrew things?? Why not learn how to "homebrew" antennas??

Dg9bfc

Sigi

ps mmana is freeware and easy to use ... with LOTS of ready to use models in it.....

30816. Folded monopole for portable use

Yahoo group: ham-antennas (2014)
Date: 2014-01-09 00:09:31 UTC
From: <farrerfolks@...>
Topic: 30816 Message: 30816

Hello all,

I am interested in finding a solution for the portable use where the antenna is NOT a simple whip, but a folded type to ground. That is, if we look at a simple whip, then look at the possibility of making it a folded mono pole and resonant it against local ground. Anybody got ideas???

Mel, K6KBE

1) try reducing the number of turns (may give poorer performance at the lower frequencies)
2) Different spacing between the two wires (lowers the mutual capacitance ...may also give poorer results at 1.8MHz)
3) 61 core material may work better at 29MHz but much poorer 7MHZ and below

Ok I'll give that a go Dave. I just wonder how other companies who make Baluns get the results of 1:1 across all the frequencies... or do they? What core would you suggest for 300w? I thought the FT 140 would be good and a t-200 for 600w max. Would be interesting to see likes of the mfj balun and what core it uses and turns etc.

On Thursday, 9 January 2014, 16:38, Artek Manuals <nr1dx@...> wrote:

1) try reducing the number of turns (may give poorer performance at the lower frequencies)
2) Different spacing between the two wires (lowers the mutual
capacitance ...may also give poorer results at 1.8MHz)
3) 61 core material may work better at 29MHz but much poorer
7MHZ and below

I build all my own baluns and a few for some club members. I got started when I bought a 4:1 and it was pure junk when I tested it. You can adjust the sweet spot by adjusting the number of turns. If I am working standard bands I set the sweet spot at about 10MHz , you might go a little higher if you work more 10M than 80M. Keep a eye out for yellow torrid if you work 10 and 6, red for the lower bands.

Here is a picture of one I was working on,

http://s1102.photobucket.com/user/KD0ZZ/media/Balunjpeg_zps41dd0ff6.jpg.html

I also made a 4:1x1:1 switchable for my ladder line antenna

Hi Rich

Thanks for the reply. I see alot of people use two 1:1 Baluns together for their own 4:1 Balun. That's an option that I'll probably go down as currently I'm only using one toroid core.

30828. mfj 2286

Yahoo group: ham-antennas (2014)
Date: 2014-01-09 20:30:00 UTC
From: bartenderjim
Topic: 30828 Message: 30828

Hi all,
I recently received an MFJ 2286 (http://www.mfjenterprises.com/Product.php?productid=MFJ-2286) for Christmas. Nice antenna it seems from all the reviews I have read on different sites. I plan to use it as a permanent setup at my home QTH along with my G5RV,jr. that is setup in inverted V with center approximately 20' and ends about 8'. I have it ground mounted with 2 radials setup east and west and I cannot put any north and south due to space restrictions.

Couple of questions for anyone in the group that has used one of these:
1) If I am going to use only 20-6 do I need to use the coil? With the supplied radials or not?
2) I have a brother that is using the Hy-GAIN 19AVS (I think that is the model he said) he leaves clipped to 20M coil and uses his tuner for all from 40M down. Would this antenna also act the same. There were not a lot of instructions or information about this particular antenna.
Any thoughts or any information would be appreciated.

Billy

You can see from this picture and others in my album that I have tried more than one type.

http://s1102.photobucket.com/user/KD0ZZ/media/BalunParts.jpg.html

The first was a 4:1 voltage on a single core, then two current 1:1's on a single core made into a 4:1, the next better step, then 2 cores and I got better SWR spread on the duel rod 1:1 into a 4:1. I don't have a lot of test equipment but just using a MFJ 259B and carbon resistors. I have no information on the rods, 10MMx180MM rods are Russian military I bought from a Lithuanian ham on E-Bay, and some 1/2dia rods from K5EST , hamfest stuff. I enjoy stuff and making things.

I love making things too. That really is a must for ham radio. Build antennas not buy antennas. I suppose i'll just need to experiment with different cores and wires for windings see which is best for a low swr reading across the bands.

Hello James,

Are you going to be using a tuner with the 2286? Without the coil the lowest frequency for 17 feet is 14.47 MHz. I think that the operation of the antenna will be a little compromises on 20 Meters as the manual says you need 5/8" of L1 to get to the CW portion of 20 M. If you are going to use a inline ATU, then it will probably allow the 20 M coverage without the coil.

Rich,
I think a ham antennas group net would be a good thing. SSB would be best for me maybe 2 nets one CW and one SSB...and maybe even one digital..that way we could try out all our skills and antenna designs on all modes.
Just a thought.

30839. Stealth Antennas hidden in Trees

Yahoo group: ham-antennas (2014)
Date: 2014-01-10 02:58:26 UTC
From: <kl7rs@...>
Topic: 30839 Message: 30839

Does anyone know if an antenna hidden in a tree can actually catch the tree on fire?

What precautions if any can eliminate or reduce the chance of this happening. I'm curious because a lot of people are living in HOAs these days and are forced to put up stealth antennas and I can only assume most of these stealth antennas are going up in trees.

From: Frank Kirschner
Topic: 30839 Message: 30841

Yes, if you're running high power and the antenna isn't adequately insulated from the tree, and conditions for a fire are present (dryness, etc.), it could happen. I seem to remember reading at least one account of a tree (maybe it was a fence post) that caught fire as a result of proximity to a ham antenna.

If the antenna is on stand-off insulators, even an inch away from the tree, and the antenna itself is insulated (as opposed to bare wire), that would greatly reduce the danger.

Topic: 30839 Message: 30842

The short answer is yes under the right conditions you can start a fire. The higher the power the greater the risk.
I had a an elevated ground plane mounted on a wooden fence. One evening on 80M, CW, running a KW I set the fence on fire. The insulated radial wires were simply stapled to the fence and at one point a couple of radials crossed over each other which was the apparent point of insulation breakdown and ignition. Fortunately (?) the window in the shack over looked the back yard and the fire immediately caught my attention.

That being said a modest amount of care to make sure that the wires are a couple of inches from actually touching anything even with the wind blowing, tree swaying etc and you will be just fine.

Hi Mel,

a good starting point may be G5IJ antenna, which seems to me a multiband fodlded monopole. You may read
http://www.gairney.plus.com/Radio/G5IJ%20aerial.pdf
http://www.gairney.plus.com/Radio/G5IJ%20aerial.pdf

another known example of vertical multiband folded monopoles may be the RXO Unitenna, read
http://www.standardtrees.co.uk/RXO-Unitenna.pdf
http://www.standardtrees.co.uk/RXO-Unitenna.pdf

Both G5IJ and RXO refers to a non resonant antenna, but may give you some ideas.

another nice source of ideas may be the paper of three Japanese professors titled "Double-folded Monopole Antenna with Coaxial Cable" google this title to retrieve it. It's a very interesting analysis of building RESONANT folded monopoles using coax cable to reduce size and I suggest to read it.

What is the impedance of the antenna at the feed point, since you've mentioned what size and bands you will use?

Are you using some type of impedance matching or tuner at the base of the antenna?

If you are using a tuner with a balanced output, there is an old trick where you can run two coaxes, which sort of makes a balanced feed, or think of it as a shielded ladder line. This is exactly what I did for a 100' run to an extended double zepp antenna and it worked like a charm. At the antenna the coax center conductors feed your antenna, and the shields are tied together but to nothing else. At your tuner in the shack the centers go to the balanced outputs, and the shields both tied to the case of the tuner. Using this balanced feed method will work much better than trying to use one coax to feed an antenna that isn't the same impedance as the feed line; you'll have problems with the coax radiating and unexpected results.

I like your thinking Allan, not so long ago I was messing around with some old wire antenna designs ready for a quick deploy when we move qth hopefully very soon, I came across some old plans showing exactly what you describe and I can confirm it does work very well with twin feed 75ohm coax, infact it worked better than my 40m inverted V both rx and tx, its now coiled up in a bag ready for the install at the new qth when we finally get moved, here is a link to what I built (I used the old pdf pages shown not the newer version)
http://www.southslope.net/~kb0sk/antenna.html
and being short of funds used this to bring the dual feed back down to a short single 50 ohm coax feed into the shack (not the best I know)
http://rogertango.com/articleread.aspx?idnumber=34232411

An easy build with decent results well worth a try for anybody looking for a multibander a bit shorter than what is normally required.

Hi Billy, I had the same problem with a 4:1 that I purchased (never again) so I built this as a temp solution:- http://rogertango.com/articleread.aspx?idnumber=34232411 Works great from 10m to 20m ok on 40m not much good after that but is cheap and easy to make, they get some stick on forums as being no good but it works for me cost nothing and is better than the rubbish in a little black box I was sold, I use it on one of these:- http://www.southslope.net/~kb0sk/antenna.html Which is fed with aprox 25ft of twinsat 100 75 ohm coax then with the balun is reduced to a short single feed of mini 8 50 ohm into the shack, works very well for me. Phil M6MRP --- In ham-antennas@yahoogroups.com, Billy McFarland wrote: > > I've just tested the balun. FT-140-43. With a 200 ohm resistor across it at 1.9mhz it's sitting 1:1 swr but as it goes to 29mhz it's sitting at 1.5:1. How could I get it to reduce to 1:1 at 29 MHz?

Rich,

I think we could do a net that is flexible and moves from one band to another every week. Might be a bit laborious at first but then people get to try out their antennas and experiment a bit. There are some real experts here that can offer advice and answer questions on the net. Plus it would be fun. Right now my interests are focused on 80m and trying to get this darn K9AY receive antenna working with no luck so far. Need to check the 9:1 W0BTU transformer might be bad.

How about a ham-antennas conference on Echolink? for those of us who wish to participate/discus but do not have the power advantage to get in on the action but could give interesting reports in realtime, we may be qrp but our ears are valuable tools.
A digital net sounds interesting to me and once we have moved qth, settled in and the shack/antennas are deployed I would participate, my next build is going to be a 40m-80m low power internal frame antenna and some on air reports would be nice, anybody built and tried one?

From: <kd0tli@...>
Topic: 30853 Message: 30853

KD0TLI here,

I'd like to ask if anyone has ever tried a zig-zag pattern for a desktop loop antenn rather than the typical circular spiral type. An example of the circular spiral type I'm talking about is here: http://makearadio.com/loops/index.php http://makearadio.com/loops/index.php Rather than winding in a circular spiral pattern, could a zig-zag pattern also work ? http://www.qrz.com/db/KD0TLI http://www.qrz.com/db/KD0TLI

Just curious.
Thanks.

I am having trouble visualizing what a zig-zag pattern is in this
context? Can you expand or show a picture as an example?

If it's the same as shown in the link, it looks like some antenna off a
1922 Whirlygigwhizbang Radio !!

Think of a loop with flat sides, diamond shape.

30856. Coax Feed

Yahoo group: ham-antennas (2014)
Date: 2014-01-11 20:42:01 UTC
From: dale cole
Topic: 30856 Message: 30856

Somewhere I read that coax lenght could be counter productive on certain freq. (i.e. one should avoid running 30 meter lenght of coax to a 10 meg antenna). I can't find it in my 1970 Antenna Handbook, and all the other Handbooks are buried, as I remodel the shack. I am working with a Cushcraft MA160V (using 100' coax) and a 6btv vertical also with a 100' of coax. Both are using RG-213 with 100 w and are buried. No baluns.

30860. Horrible RF noise problem

Yahoo group: ham-antennas (2014)
Date: 2014-01-11 22:25:08 UTC
From: Dean
Topic: 30860 Message: 30860

I don't know if this is right group for this or not, but maybe someone can steer me in the right direction. My Radio is the Yaesu FT-857D and works fine except that I have a massive noise problem on certain bands. I have found the big bad bear to be my 20KW inverter, made where else but in China. No filters, but it works fine! Yes, it is 20 kilowatts. IT converts 240VDC to 230VAC 50 Hz. I have about 10,000 watts of solar panels and we are not connected to the grid at all. The inverter is a big floor standing thing. This inverter makes a continuous hammering noise on certain bands that sounds like a monster woodpecker with a 2-cycle engine incorporated into his beak and it's working at a very fast speed of about 4 to 8 pecks per second,and his engine doesn't have a muffler. Not trying to be funny but that's really what it sounds like in my radio. The inverter is located about 120 feet from my house and radio shack and is inside a 40 foot container. I tested it by turning off the inverter....the radio is powered by a 200 amp deep cycle battery, and the radio was very quiet on all bands, I was amazed! So I hope someone hassome knowledge about these things that can give me some instructions or ideas. Thanks!

Hi Dean,

Quite a problem. Question, do you have a scope or a spectrum analyzer? It would be interesting if the repetition rate can be seen on the 240 DC side. It sounds more like a PWM regulator than the 50 Hz side. Can you put a serious load on the inverter to see what changes? Like a deep well pump, etc. If the rate changes then it is a PWM issue and will be much harder to address. With a spectrum analyzer you could find where the primary frequency of the RFI is and maybe address that. Careful working with 230 VAC. Good luck. Some thoughts.

Dear Hal

this is the info I have:

For longer coax and/or a different velocity factor,
the equation is:

L* = 150*(1+2*n)*VF/fo (m) n=0,1,2,3…..
   Note: Never employ a coupling coax
length near or less than l/4 !

hope this helps

Paul

BTW: the source for this is RF Laboratory practice

Hmmm....that statement seems to be an oxymoron to me..."No filters, but works fine." IMHO, if there are no filters, it is NOT working fine...but what do I know?

Yes. I understand, and I don't think it is funny either.

> The inverter is located about

40 foot: diameter?, high?, long, what? Is the "container" made of metal or some non-metallic substance?

> I tested it by turning off the inverter....the radio is
> powered by a 200 amp deep cycle battery, and the radio was very quiet
> on all bands, I was amazed!

Well, don't be. My favorite "Elmer" told me in the 1960s that the ordinary ambient noise level had risen substantially since he was licensed in the 1930s, and he attributed this to the activities of the Rural Electrification Administration...at least in the U.S.

> So I hope someone has some knowledge about
> these things that can give me some instructions or ideas. Thanks!

Well, I think we can possibly help, but you may have to dig into the unit and install some proper filters at the appropriate places. If that is impossible, then someone mentioned the MFJ 1026 active noise filter as a possibility.

That unit actually works very well for many types of noise, but is certainly no panacea either. It can also be difficult to properly configure and it really isn't proof against some types of noise.

FYI, one of our sons built a hot-rod gaming computer some time ago in which he installed a 600 watt power supply made in China. It too had no filters, and wiped out, literally, every piece of electronic equipment in the entire home, and especially my radio gear.

Once I figured out the problem, I replaced his crummy power supply with a good Antek, opened up the Chinese power supply, discovered absolutely zero filters of any kind in it, and disposed of it with some well-placed 7.62 X 54R from another son's Moisin-Nagant at 50 paces.

Of course you don't have that freedom.

Now, down to more serious help:

Do you have or can you get any sort of schematic diagram for your inverter?

Can you share that with us some how?

Is the cabinet or case of the inverter made of metal?

Do you have a good ground system somewhere nearby?

Are you familiar with the normal methods of using ferrite-filters?

Can you get, fairly easily, such ferrite filters?

Can you get or do you have some good line-voltage AC rated disk ceramic bypass capacitors? (These should be those rated for connection across an AC line so that if they fail, they fail OPEN. I forget the correct nomenclature for those, but Mouser has them. Someone else here will be able to give the correct type.)

The basic idea is to "bottle up" the noise inside some sort of well-grounded shield and at the same time, short only the RF-noise to that ground, or even to itself.

Does any of the above help?

From: Kenneth G. Gordon
Topic: 30860 Message: 30866

I might give some more details on the "bottle it up" method.

What you can try to do is to make certain your inverter is installed inside some sort of grounded RF-proof shield.

In the interests of cooling, sometimes copper mesh must be used.

Then you must by-pass-for-RF to this grounded shield all wires going into and coming out of the box, as close to the exit of each as possible.

What you want to do is to strip all the RF off any wire that enters or exits the box. You do this "stripping" with appropriate parallel capacitors, at least.

Sometimes, you also have to use series inductors, although should this be necessary, it becomes extremely difficult to accomplish mechanically, since you have to install those inductors, themselves, inside a shielded metal box, and they must be sized to handle the necessary current.

Ferrite filters which SURROUND the wire will reduce this sort of mechanical problem....IFF you can find any which are big enough.

Since it may be likely that part of the electronics in this unit consists of SCRs, you may be able to bypass the various leads of those SCRs to help eliminate the RF noise they make.

All of this may be difficult to accomplish, since you are dealing with 240 VDC and 220 V 50 Hz. AC and at least 100 amps. You must be very careful both when working with it, and when adding the RF shunts.

Then, as mentioned above, there is the cooling problem to deal with.

I think that if I had your problem, and if I could afford it, I would simply get rid of the blasted POS by selling it to someone or some company which didn't have radios, and who "lived" at least 20 miles from me, and would then buy a replacement which has the proper filters already incorporated in it.

Hi Kenneth,

And thanksfor the tips. The inverter works fine and functions perfectly if I were not a ham! The container is a 40 ft. steel container as used by ships to carry cargo. It is about 40 feet long, 8 feet wide, and 7 feet high roughly. Idon't think there is a schematic with the inverter. I can take and send some photos ifthat might help. The cabinet of the inverter is made of metal. It has slots for air circulation on all sides. I have the metal case grounded through a small hole in the container to a copper ground rod outside, however here in the desert it never rains a drop, and the ground is dry sand. I pour some water around the ground rodevery few days. Also the radio chassis is grounded outside our home the same way to another ground rod. I have no ferrite filtersand cannot get them in Iquique, the nearest sizable city to me. Tell me what I need and I canorder them from the states. I am not familiar with using those ferrite filters or AC capacitors.But tell me what I need to do and I canorder them from the states.

Yes. I understand...even so... :-)

> The container is a 40 ft. steel
> container as used by ships to carry cargo.

Ah! Yes, a standard cargo or shipping container. We use them around here
too.

How are you getting the 240 VDC INTO and the 220 V 50 Hz OUT of the
container? Please be specific.

What I am thinking is that possibly we can work out a method of "stripping"
those wires of the RF noise, while using the shipping container as the shield.

> It is about 40 feet long, 8
> feet wide, and 7 feet high roughly.

Yes. I know exactly what that is.

> I don't think there is a schematic
> with the inverter.

Usually, they don't send one with it.

> I can take and send some photos if that might help.

That MIGHT, especially if there is some sort of data plate on it somewhere
which we could see.

> The cabinet of the inverter is made of metal. It has slots for air
> circulation on all sides.

Then RF would leak out of it very badly.

> I have the metal case grounded through a
> small hole in the container to a copper ground rod outside, however
> here in the desert it never rains a drop, and the ground is dry sand.

Then you have, essentially, no real ground. This is going to be difficult...

> I pour some water around the ground rod every few days.

I pee on mine every few days...but only at night... ;-)

We don't have a dog...

> Also the
> radio chassis is grounded outside our home the same way to another
> ground rod.

Again, essentially no ground at all. We'll have to work on this...

> I have no ferrite filters and cannot get them in Iquique,
> the nearest sizable city to me.

That is completely understandable.

> Tell me what I need and I can order
> them from the states.

I'll have to do some research, and will send you photos of the small ones used to filter RF from TV sets, VCRs, etc. They work pretty well. I usually buy the ones I need off eBay. Mouser has them too...and the capacitors.

> I am not familiar with using those ferrite
> filters or AC capacitors.

OK. I'll try to get some info on those to you asap.

>But tell me what I need to do and I can order
> them from the states.

OK. Let me go to work on this. It will take a few days. In the meantime, I am going to CC this to the ham-antennas forum. Others there probably have better ideas than mine, especially with regard to your ground problem.

In any case, the voltages and currents you have to deal with are deadly, so please be very careful.

>>How are you getting the 240 VDC INTO and the 220 V 50 Hz OUT of the container? Please be specific.

The No. 12 wires from my solar panel groups all go underground through No. 32 (1") dia. Orange colored PVC electrical conduit, up the side of the container on the outside to an elbow into a wall type PVC electrical connector with a nut on it..through a hole I cut in the wall of the container, about 5 feet above ground.

From the inverter, I have a 3 wire cable, (No. 8 wires), black rubber covered, going into the same type of 1" PVC electrical conduit connector through the wall of the container, then down into the ground, buried 30" deep to my house about 120 - 130 feet away, in conduit all the way.

Note: there is no conduit inside the container between the wall and the inverter, as the inverter sits about 3" from the wall.

Just a quick update. My makeshift K9AY loop is a real eye opener. It totally works. Reduces noise by about 1-2 S units with receive signal strength being the same as my sloper. For such a basic and simple antenna, I have to admit that I am totally shocked that my homebrewish receive antenna actually works.

I got the design primarily from the ARRL antenna book with help from the on4un book and a PDF I found on the web. This is epic!!!

From: Jim
Topic: 30856 Message: 30872

Hi Dale,

Wellllll..... a little thought problem. Lets put an MFJ259B analyzer on the end of a 10ft piece of 50ohm coax and connect the other end to a load like the old Heath Cantenna, which was 50 ohms at HF. If we look at the SWR on the 259B, we should see a 1:1 SWR, or something very close, at any frequency between 2 and 30Mhz. Now lets make the coax 100ft; that is 10x longer. Will we still have a 1:1 SWR at Hf? Sure we will and it will be the same from 2-30mhz!

So what would be wrong if there was a different reading if we varied the transmission line length and the SWR changed? The "antenna" would have to be part reactive, either capacitive or inductive; at resonance those factors should cancel out and just leave the resistance.

I don't know anything about the MA160V, but do have a 5BTV. It is a trap antenna and is designed to be about 50ohm input on its operating bands. However, that can vary slightly, depending on its radial field.

Varying the length of a transmission line is not necessary when an antenna is operating at a resonant frequency. It is usually done when the antenna has reactance at the operating frequency and the transmission line length is used to transform the impedance seen at the transmitter.

I operate my 5BTV on 60m by using an antenna tuner. The transmitter is happy and the antenna has done very well. The run from the shack to the antenna is about 160ft; the coax is buried 1ft under the surface of the yard.

So, don't worry about the length of the lines.

Hi Keith,

I like loops over dipoles depending on how their hung depends on the angle if radiation but can be good for dx. I put up a delta loop and my house and replaced the dipole reduced noise by three s stops which was a life safer as the noise at my qth can be bad at times.

Did you use a section of 75 ohm feeder for matching or a 2.5:1 balun. I prefer the latter as for low frequency you don't need a long length if matching coax. For multi band use I prefer a 4:1 balun. I've always used 14 awg speaker wire, cheap and strong enough for the local winds.

Dean,

1) Try leaving the inverter running but with the output wires
disconnected.
2) Is the container itself connected to the ground?

This is going to be tough one to solve (you knew that :-))

The noise can be transmitted via radiated and conducted paths (likely both to some degree). I suspect that the noise varies in strength depending on the load on the inverter as well. Conducted noise, noise leaving the box via the wires (into and out of the box) is the easiest to measure and filter and I would start there. Noise being conducted over the I/O DC & AC (and control?) lines is the easiest to stop and this noise uses the wiring in the whole system as an antenna which your transceiver is picking up. Radiated noise is noise that uses the internal wiring to the cabinet as an antenna the cabinet may or may not be good enough to stop this

For starters (if it were me) I would get a good oscilloscope (100 MHz bandwidth or more) and if possible a spectrum analyzer and characterize the noise. you should be looking at the total spectrum and bandwidth of the noise as well as individual spikes and other non sinusoidal garbage riding on the waveform. Take measurements under with minimal and full load. This will help you decide what kind of filters you actually need, and will give you quantitative measures of how effective a given filter is. lots of commercially available filters (mostly low-pass) but you may decide that a few home brew notch filters just for ham band frequencies is more effective. Get a notebook, keep good notes (notebook) and take lots of digital photos of waveforms before and after

Once you have eliminated the conducted noise and you still have problems then you are looking at improving the shielding on the box..the subject of a another email when you get to that point

I agree with Dave but think the characteristic of the noise you have is like a motorboating effect. That leads me back to the regulator circuit that is not smooth but pulsing to cause a low frequency oscillation you describe. You don't need much phase shift in the feedback circuit to allow the instability or pulsing. Looking at the block diagram the sensing circuit already has a series cap going to the op amp if the microprocessor controller has any more, it could be your source problem.

This will help you decide what kind of filters you actually need, and will give you quantitative measures of how effective a given filter is. lots of commercially available filters (mostly low-pass) but you may decide that a few home brew notch filters just for ham band frequencies is more effective. Get a notebook, keep good notes (notebook) and take lots of digital photos of waveforms before and after

Once you have eliminated the conducted noise and you still have problems then you are looking at improving the shielding on the box..the subject of a another email when you get to that point

Mark, and all:

From Dean's description, I believe his ground system is not effective. At this point I am not sure what can be done about it either.

Secondly, I also believe there are two ways to attack his problem. both of which have been covered pretty well here: 1) bottle up the noise inside an RF-tight box, 2) attack the source of the noise by looking closely at the circuit and any possible defects with it.

As Dave also mentioned, the solution to Dean's problem is NOT going to be easy, but I am also sure it can be overcome, given enough time and energy.

All,

I've put together an portable endfed antenba set up as a slopper. Worked very well and takes minutes to out up. Here's a video of a friend setting it up.

Subject: [ham-antennas] Re: Coax Feed

Hi Dale, Wellllll..... a little thought problem. Lets put an MFJ259B analyzer on the end of a 10ft piece of 50ohm coax and connect the other end to a load like the old Heath Cantenna, which was 50 ohms at HF. If we look at the SWR on the 259B, we should see a 1:1 SWR, or something very close, at any frequency between 2 and 30Mhz. Now lets make the coax 100ft; that is 10x longer. Will we still have a 1:1 SWR at Hf? Sure we will and it will be the same from 2-30mhz! So what would be wrong if there was a different reading if we varied the transmission line length and the SWR changed? The "antenna" would have to be part reactive, either capacitive or inductive; at resonance those factors should cancel out and just leave the resistance. I don't know anything about the MA160V, but do have a 5BTV. It is a trap antenna and is designed to be about 50ohm input on its operating bands. However, that can vary slightly, depending on its radial field.
Varying the length of a transmission line is not necessary when an antenna is operating at a resonant frequency. It is usually done when the antenna has reactance at the operating frequency and the transmission line length is used to transform the impedance seen at the transmitter. I operate my 5BTV on 60m by using an antenna tuner. The transmitter is happy and the antenna has done very well. The run from the shack to the antenna is about 160ft; the coax is buried 1ft under the surface of the yard. So, don't worry about the length of the lines. 73, Jimmie, K9JFK --- In ham-antennas@yahoogroups.com, dale cole <dchamguy@...> wrote: > > Somewhere I read that coax lenght could be counter productive on certain freq. Is it safe and plausible to reverse an antenna switch? I haven't tried it yet, but would like to know, if I could safely use two transceivers and one antenna? Please, be kind with your answers. If there is a switch that can isolate the signal and not allow the other transceiver to be overloaded, even though it is turned off, I would be interested in that switch, better yet, if I could have both turned on.

Thanks,

Keith

Hi Bob,

Not trying to start a fight here-- but out of curiosity, why would you post an advertisement here, then not answer email sent to the address from which that advertisement was sent, and then later when someone comments on your not answering, post a comment saying "not surprising", indicating that no one should be surprised you are ignoring the address from which you sent the advertisement in the first place?

I would think it surprising that you would not answer the address from which you posted...

Hi Dean,

Here is a thought.

Are you using a desulfinator on your battery plant?

I know if I run my desulfinator, which works via a high frequency voltage pulse to the batteries, that I will get a pulsed RF signal back out the battery feed cable. I just turn off my desulfinator when I use the rigs to avoid the rhythmic pulse noise here.

It drove me nuts before I found the source RF and several harmonics by hours of sniffing. No filtering, no capacitors, nothing will stop the noise in my plant except temporary disconnection of the defulfination unit.

I have a fan dipole fed with 100 ft of coax that I didn't cut because I was finalizing the details of the structure of the support system. Now I am ready to cut it, but:
1. do you calculate the 1/4 wavelength for the lowest or highest frequency?
2. I have a balun made from 18 turns of the coax--do I include that in the overall measurement?

I just want to follow the old axiom "measure twice, cut once".

Hi Dean,

I am very familiar with poor grounds in the desert having lived in Arizona for 60 years.

One trick you can try that I used with great success is to run a PVC pipe(start 2' from top fill cap to *drill 1/16"* or smaller holes down the side that will be facing the ground rod staggered off the center line about 1/2" about every 3") (Size of pipe your choice depending on how often you want to refill it or what you have on hand.) into the ground within 5 to 6 inches of the ground rod (I tape a piece of 1/4" plastic tube to the side or the PVC and finish with a piece of 1/4" copper for the last foot to the end of the PVC then over the end to a point about 3" below the cap on the bottom of the PVC pipe) I then use water pressure through the 1/4" line to "Drill" the PVC pipe into the ground. *It is slow going!* But it works. I try to leave at least 6" above ground and go 2' past end of ground rod. If you don't mind water works use a temporary cap and fill the PVC tube with water under pressure to help drill the hole for it if you have the water available.

After it is drilled into the ground fill with water and check every few days to see how fast it uses the water.

Hope this helps some

72

Hi Bob,

Not trying to start a fight here-- but out of curiosity, why would you post an advertisement here, then not answer email sent to the address from which that advertisement was sent, and then later when someone comments on your not answering, post a comment saying "not surprising", indicating that no one should be surprised you are ignoring the address from which you sent the advertisement in the first place?

I would think it surprising that you would not answer the address from which you posted...

Hi Dale,

I don't think the vf of the transmission cable will ever be a problem if the coax is terminated at both ends in a value that equals its characteristic impedance. Don't forget, the antennas you have are designed to be multibanded and resonant at the frequencies of their operation.

There are many antennas around that change the length and type of transmission line to match the antenna to the transmitter at the frequency of operation. One of these is ...

http://www.w5dxp.com/notuner.htm

Would've liked to try that one, but don't have the proper supports for installation.

Joe,
You mean that stuff that when it is wet is slicker than "Black Ice"?
Yes it is a pita in both respects.

It can be done if it is a layer about 2 ft. thick, past that find a drill machine

I taught my daughter to drive "Like on ice" on that stuff and told her "If you get us stuck you dig it out".
She never got stuck and now living in MI I have never seen her have a problem driving in snow or ice.

Keep the dynamite handy when working with that stuff or *tons* of water to soften it a couple of inches at a time every 24 hours.

30902. RE: [ham-antennas] Re: Coax Feed

Yahoo group: ham-antennas (2014)
Date: 2014-01-13 12:50:15 UTC
From: Richard Schmuke
Topic: 30856 Message: 30902

I have made fan dipoles. Cut the lowest frequency first, from that point on all the higher frequencies will interact depending on the spacing to the lower frequency wire. Longest wire first and work your way up. Here is a picture of my 5 band dipole. I used 14ga copperweld for the 80M wire and regular copper for rest of them and it has held up thru several ice storms.

http://s1102.photobucket.com/user/KD0ZZ/media/DSC00947.jpg.html

F/B on the coax balun. The important measurement is make sure the coax reaches from the antenna to the radio, HIHI. If you were trying to adjust a coax length for some reason all the different frequencies would make that almost impossible.

Subject: [ham-antennas] Re: Coax Feed

I have a fan dipole fed with 100 ft of coax that I didn't cut because I was finalizing the details of the structure of the support system. Now I am ready to cut it, but:
1. do you calculate the 1/4 wavelength for the lowest or highest frequency?
2. I have a balun made from 18 turns of the coax--do I include that in the overall measurement?

I just want to follow the old axiom "measure twice, cut once".

30904. Antennas update

Yahoo group: ham-antennas (2014)
Date: 2014-01-13 14:01:10 UTC
From: Keith Heimbold
Topic: 30856 Message: 30904

It was an antenna weekend and my wife and son were cool for letting me do a little antenna work.

I built a homebrew K9AY receive antenna using 85' of stranded 14 gauge wire I had lying around along with a W0BTU transformer with enclosure I bought for a failed beverage antenna project (in the canyon project), and a couple 1k ohm resistors in parallel I had from that failed experiment. I have it mounted on my MFJ pole to the corner of my gazebo and I grounded it to my chain linked fence with a connected ground strap and also a second solid 12 gauge wire. All I can say is wow! It works! Some signals are one to two S units stronger in direction it is pointed but more importantly background noise levels are 1-2 S units lower. Readability of signals is so much better with lower noise. It really is a bit of a miracle antenna and I am still on shock it works that well.

On Sunday I installed my new to me Mosley Pro 57B. I would call it 80% completed. Tests were all fine though 10m is a little low in the band dips at 28.050 MHz. Nevertheless I won't mess with that. I am starting to focus on CW so I will keep it there. I posted a picture of me working on it yesterday on qrz. Once I finish a couple tweaks I will push up the mast to final position and install the rotator. So stoked to have 10m&12m back. I now have antennas for 160m to 6m for all bands but 60m.

Digging holes in the flat lands of Az is definitely a challenge, I used to live up the road from you in Mesa

I took out an old (and disfigured) 40' tall Eucalyptus tree and replaced it with a large Olive tree. I paid somebody to remove the Eucalyptus and then proceeded to dig a 3' deep hole for the Olive....Should have done it the other way around (i.e take down the Eucalyptus myself and pay someone to dig the hole). To close to the house to use dynamite and the XYL was to paranoid about even allowing a pneumatic jack hammer that close to the house (lots and lots of glass) , I ended up using a masonry drill to drill holes in the caliche and then broke it up with with a star chisel and a sledge hammer...took me a week to dig a 3' diameter, 3' deep hole for the olive :-(

Dave,

LOL, I graduated from Mesa in 1964 "Old Mesa High 2nd Ave and Center then saw it buring to the ground from a 727 returning to Phoenix after asking my classmate to marry me" so I had a lot of experience digging in that junk. Best way was to start a hole fill it with water, then next day dig it out refill and go back 24 later and take out another 6" or so until you get down about 2 feet then it would go faster unless you had dynamite or a jackhammer something a teen doesn't have.
We did have access to some alligators that year though. [?]

Yes the container can act as a faraday cage ...

But you have to add copper mesh to the ventilation holes maybe

(try the filters first ... maybe you can forget about that copper mesh)

You have to use filters on the solar and power line wires (input and output filtered that nothing can come out on either side of you private power plant)

Corcom makes very nice filters for single phase or three phase nets ... you should buy some good 100amps filters from them

60 db damping and more is possible from 100kc up to 100 megs

I would add filtering on solar plus and minus (yes on both ... just to be safe)

And also on the power line to your house ... maybe another one at the house entrance ... then it should ne quiet like in a church :-)

You can then additionally add a smaller filter in your "fuse box" after the fuse to your shack (so shack is additionally filtered) ... maybe 10 or 20 amps (depends on house wiring)

At what height did you measure the mosley??

If low to ground that may be a reason for that low resonance

30911. windom antenna help

Yahoo group: ham-antennas (2014)
Date: 2014-01-13 17:01:34 UTC
From: Robert Moss
Topic: 30911 Message: 30911

I am attempting to put up my 80-10 meter Carolina Windom in a small amount of space and have a question about what the best configuration would be. I have two trees about 50 ft tall that are approx. 90 apart. The antenna is 132 feet long and I want to support as much of the antenna as possible between these two tallish trees. My question is what the best arrangement is for the remaining 42 feet of wire (132 - 90 = 42) that will have to bend in some direction.

1) Should I let the end portions of the wires hang down vertically parallel to (but away from) the tree trunks?

2) Should I keep the end portions of the wire horizontal and bend them toward another support like a tree or the house.

I've got a window of 2-3 days with milder temperatures to get the antenna up and I hope somebody can head me in the right direction before the thermometer begins to plummet.

Many thanks!

73, Bob W1RAM

Hi bob,

I would go with option two. Bend the elements and guy off at the same height if possible. I would go away from the idea if bending the elects towards the ground.

I suspect that is what they are doing....suggestions for getting grounds into a dry ground to *create* a good ground, to possibly control the high RF noise problem...It *was* mentioned that extremely dry areas, like deserts, present 'issues' in providing good grounds.....so digging IS a good topic, that should not be curtailed.

Instead of talking about that ground and how to dig a hole in it ... we should talk about how to get rid of that noise

30914. Re: [ham-antennas] windom antenna help

My thought would be to 'slope' the 'leftover' wire..making sure to tie it off with dacron rope or similar, so the antenna does not attach directly to the fence or house, or what ever it will be attached to. Should work just fine.....

I run a Carolina that I have on 16 foot 2x2 redwood poles, going around my back yard fence...it looks like a big U from above...works great.....As your will have a goodly portion up 50 feet, yours will perform even better than mine!

That good ground will not help if the rf noise travels out of the container
along the power line or solar lines

So first of all you need filtering ...

The filters have to be grounded ... so yes you need a good ground ...

The antenna will have alonger and a shorter end

Pull your balun in one of the trees and the end in the other tree

Tie the shorter end to another tree (if available) or the house or ....

Should work well

Good, on ya, Sigi.

You said in far fewer words than I the same thing I have been trying
to say for days.

Good man.

You *can* generate a capacitive coupling to earth with a bunch of radials that go out extended distances.. along with several *long* ground rods...

In Florida, a great ground was only a few feet away. Despite that, radio stations typically had 120 radials going out at least as far as the tower was tall.... The best ground were salt marsh areas where you could get the ground into a nice soggy, somewhat salty moist ground...but for stations where there was no water close to the surface, simply having tons of coupling worked well. (in many cases a 100-300 square foot of copper chickenwire, with the radials welded to it periodically, all the way to the ground point for the towers.) - If at first you don't succeed with one ground rod, grow the ground.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

30920. Re: AW: [ham-antennas] Antennas update

Yahoo group: ham-antennas (2014)
Date: 2014-01-13 18:12:30 UTC
From: Keith Heimbold
Topic: 30856 Message: 30920

Initial measurements are at approximately 25'. Once I finish tweaking the antenna it will be at final height of 35'. I am completely cool with the swr currently. If it improves or changes slightly up band great. If it decides to move down band as I raise it I might have an issue. My plan is to use this antenna primarily for 15,12 &10. It is also a great match on 6m which means nothing from a pattern and gain perspective but probably gives me another listening antenna to use when I am pointed in the opposite direction with my innovantenna six element OP DES. For what I paid for the pro 57b, almost free it is going to be perfect for my needs.

There is a pic on my qrz that shows you where the antenna is mounted currently.

Yes the balun at a tree with the long element hung out like a dipole. The other smaller section tied out to another tree or house this would be slopping I would imagine. So from a birds eye view it would look like an L shape

Joe, that's good to know. Bending the wires does not seem to be a problem. If I had a choice between dropping the end down like an inverted V or keeping it horizontal and going to another tree, Which would you favor?

Horizontal for me as high as possible. Even if the smaller side is slopping a little that's fine. Bending the elements at 90 degrees to each other at the ends doesn't effect the antenna that much but for the window the longer element look at that to be the part doing all the work so sigi suggestion would be better if you can accommodate it at your qth.

Billy

My longer wire would run in a North - South direction whereas the shorter one will be East - West. When you say that the longer wire will be "doing all the work," I think you're saying that the longer wire will be radiating essentially broadside to the wire on the lower frequencies and will develop multiple lobes, some of which will be more off the end of the wire. The shorter wire radiates in directions that are different from the longer wire and may produce either nulls in my antenna's pattern or actually make the antenna more omnidirectional, depending on the band. Does this sound right to you?

Radiation broadside to North - South seems a good arrangement for me. I'm located north of Boston very very close to salt water and beaming due west from here most of the the USA but with a slight detriment right down the east coast toward Florida.

I appreciate all the help you're giving me!

From: Billy McFarland
Topic: 30911 Message: 30926

Bob that sounds right to me. The longer element north to south radiating east to west. The shorter element if it's at 90 degrees to the radiator will radiate north to south so would effect the longer radiator to a degree. Maybe you could put the shorter radiator more of 45 degrees rather than 90 degrees or so.

Trial and error I think Bob

From: Will
Topic: 30860 Message: 30927

My tuppence worth,

Can you put a decent "earth wire between container and house? If you already have an earth beside phase and neutral, how big is it? Just regulation size?

I'm thinking a piece of the copper strap as used as lightning conductor. i.e. about 2 inches wide by 1/8 thick.

That would put both house and container 'earths' at same potential. Wouldn't need to worry too much about the actual ground any longer.

Cheers
Will

>
> In Florida, a great ground was only a few feet away. Despite that, radio stations typically had 120 radials going out at least as far as the tower was tall.... The best ground were salt marsh areas where you could get the ground into a nice soggy, somewhat salty moist ground...but for stations where there was no water close to the surface, simply having tons of coupling worked well. (in many cases a 100-300 square foot of copper chickenwire, with the radials welded to it periodically, all the way to the ground point for the towers.) - If at first you don't succeed with one ground rod, grow the ground.

30929. Alpha 6160 construction

Yahoo group: ham-antennas (2014)
Date: 2014-01-14 12:31:39 UTC
From: Billy McFarland
Topic: 30929 Message: 30929

All,

I'm thinking about constructing an antenna similar to the alpha 6160 it uses a 4:1 unun. I was wondering if anyone knows the exact total length and the length if the matching section (ie twin wire section)

Thanks in advance

73 de GM0OBX billy

30931. Re: Horrible RF noise problem

Yahoo group: ham-antennas (2014)
Date: 2014-01-14 14:06:48 UTC
From: Dave Rickmers
Topic: 30860 Message: 30931

Your RF ground doesn't need to be anywhere near the earth. Most antennas are asymmetric dipoles. If you raise your "radials" and feedpoint to "overhead" the requirement for radials drops 75%. If a "ground" conductor is longer than a quarter wave it behaves more like an antenna. Mains safety grounding, lightning safety grounding, RF grounding are 3 distinct systems. Code requires they have a DC bond to trip breakers and GFC Interrupters. Do not expect the Mains ground to help with RF, at all.

Chokes below the feedpoint are very helpful. Just some random off the top of my head. 73 de dave kd6il

30933. Re: [ham-antennas] Horrible RF noise problem

Yahoo group: ham-antennas (2014)
Date: 2014-01-14 16:14:35 UTC
From: Hop - AC8NS
Topic: 30860 Message: 30933

Dean,

I have read the useful suggestions others have made in this thread, but I haven't seen any real troubleshooting advice yet. You have isolated the woodpecker to the Chinese inverter, but you still need to run that sucker to ground (pun intended) to kill it. In the end you might have to put a copper screen-wire Faraday cage around the entire inverter and filter every line into and out of the cage.

My troubleshooting suggestion is to use your FT-857D (powered from a small 12V battery) as a portable hand-held RF "sniffer" to find out where you need to apply line filters and/or copper screen Faraday-cage shielding. Use a stubby untuned antenna, perhaps a "rubber ducky" whip or just a short length of wire (maybe a small loop) soldered to a PL-259 antenna connector. The idea is to cut receiver sensitivity down enough to allow you to explore the "near field" of the interference without overloading the front end of the receiver. With the inverter operating, tune to a band that provides a clearly audible "woodpecker" interference signal and explore to see where it is radiating from. Then start adding filters. I would opt for commercial filters with published attenuation specifications.

As a last resort, you can probably successfully build your own Faraday cage, but pay attention to well-soldered joints at the edges. As a first resort, if you have really deep pockets, small sheilded rooms (Faraday cages) with solid double-layered walls are commercially available for assembly on site, complete with RF-gasketed door, RF filtered ventilation ducts, and line filters. I worked in one of these forty years ago, a cube about ten feet on a side erected in our electronics lab for metrology work. I can testify that NOTHING gets in or out from DC to light with the door closed. Well, light does make it through the RF honeycomb ventilation ducts, but it is like looking through a kaleidoscope. And very nicely filtered sinusoidal 60 Hz AC line power came in through the power-line filters too. Other than that, very quiet in there.

Good luck on solving your problem!

Has anybody used an Alpha 6160 antenna or one of a similar design? Does this antenna design actually radiate well on a number of bands? Or is low SWR its main claim to fame? I note that it has relatively few reviews on QRZ.com.

Bob,

I've made a similar design and it works well. It's 30m long over all length 10m matching section 20m radiator section. Works 80-10m. There's a file in the group files of the radiation pattern.

Billy,

Alpha makes a Jr. and a Sr. version of the 6160 JPole antenna. The former is about 35 ft long while the latter is around 70 ft. Wouldn't the longer Sr. version get out much better on the lower bands, being twice as long? Some reviews on eHam seems to suggest the opposite and it sounds illogical to me. Do you know the Alpha antenna well enough to know the answer?

Thanks again,

Bob W1RAM

Bob,

The 75long antenna would be the better option in my opinion for putting signals out especially on the lower bands. On higher bands their multi lobe.

I don't have both to compare but logic tells you bigger is better for this type if stuff. A lot depends on configuration as well the matching section vertical and then sloping the rest is the best angle for dx contacts. I've just made one if my antennas which is 30m overall which is on its way to st Helena ZD7DC.

Hello Bob,

Take a look at the manual for the 6-160.

http://alphaantenna.com/documents/Alpha%20Antenna%206160.pdf

The antenna does need a tuner. See the SWR chart.

Billy,

That's what I figured but thought I'd better ask. I'm stymied getting my 130' windom up on account of all the tree branches and was thinking that the 70' Alpha might be a good alternative. In that case, I'd put it up as an inverted L, fed at the bottom, feed point about 20' above the ground, up over a branch about 50-60 high, then horizontally for another 35' toward the house. I've been told that it doesn't need a counterpoise to be effective (similar to the LNR EndFedx halfwave antennas.

Wouldn't the longer Sr. version get out much better on the lower bands, being twice as long? Some reviews on eHam seems to suggest the opposite and it sounds illogical to me. Do you know the Alpha antenna well enough to know the answer?

No the matching section is on the earth side if the unun. So for example 75 overall length 38 ft matching section. Inverted l will be fine but slope the long section down towards the ground maximum of 45 degrees for best performance.

As Mel said the manual of the alpha shows swr about 2:1 so tuner will be needed.

They say it is a cross of a J and Zepp. Sounds like double talk.

```
_____________________________________________________

X                ]

                                                              _____________X________]
```

I think it is probably a little like this where the 4:1 feed is at the X and the ends] are shorted. Classic J if it is. Can't be sure with out a picture from someone who has one. Anyway, it needs more info to discuss.

I think you may be right Mel. If you zoom into the photo attached one element is slightly longer than the other. But this may be because the wire goes through a dog bone for hanging. Either that it's fed at the end with a 4:1 unun and it has a matching section alike a Hooke and that's the cross between antennas.

Hello Dale,

To answer your question, we need to see the physical construction of the antenna and how it is hooked up. The description in the manual is vague on the schematic of the antenna. The reason for our query, is that a classic J antenna would have to be 3/4 wave long. That's 202 + feet for 3.5 MHz not 75 feet as advertised. Obviously they are doing something very clever and we are very interested in what that is.

Mel, K6KBE

30957. Re: [ham-antennas] Alpha 6160 construction

I wonder if it isn't shorted and the 1/4 wave matching section is just connected to the shield side of the 4:1 unun giving more of a OCF dipole type but both radiating wires a parallel rather than horizontal that would give a length of around 105 ft?

Update.

I called Alpha Antennas and talked to, Steve the owner, and discussed the interest in the 6-160 but was unclear as to the actual design and schematic. He was very upfront and will send me a schematic/picture of the antenna layout shortly. There was quite a discussion on the feed system and matching network that the antenna has that is not just a balun. More to follow.

Welding wire will work fine. Here is a close up of a 2M vertical made with SS welding wire.

http://s1102.photobucket.com/user/KD0ZZ/media/DSC00811.jpg.html

Do not confuse mild steel mig wire with a copper flashing as the same as copperweld wire antenna wire. Carbon steel welding wire with a copper flash will rust if used outdoors. If you want to use steel wire, electric fence wire is not a prone to rust. Aluminum wire will work as a coil on PVC also. I have used safety wire for a quick coil but I don't recommend it due to high resistance because of the composition but it does not rust.

I even use the High Voltage insulated fence wire for pass-through wire on car bodies. I just keep it short length. I think everyone knows about the cheap priced fencing insulators also.

Ditto on the electric fence wire. I've use it for both 80 meter loops and 160

meter dipoles. It's available in 14 awg and 17 awg.

Most wire can be soldered with the right solder and flux, even aluminum and SS. Here is a picture of a 2M vertical where I attached the 1/8” element to the 1/16 upper element.

http://s1102.photobucket.com/user/KD0ZZ/media/DSC00812.jpg.html

It is not a butt joint, I did drill a 1/16 hole in the end of the 1/8 rod. The rod material is stainless steel and 60/40 solder .If working on a large loop or other antenna than can be a long distance from the soldering iron then split bolts can come in handy. Most big box hardware stores carry a good selection of sizes.

I recently started using #14 stranded black single covered wire sold by DX Engineering. It is relaxed wire in that it's not prone to recoiling like say #12 or 14 stranded house wire that one would buy at Home Depot or Lowes. It's comparable in price to what's at Home Depot and Lowes.

Update.

I called Alpha Antennas and talked to, Steve the owner, and discussed the interest in the 6-160 but was unclear as to the actual design and schematic. He was very upfront and will send me a schematic/picture of the antenna layout shortly. There was quite a discussion on the feed system and matching network that the antenna has that is not just a balun. More to follow.

Of possible interest to the group: There is a technical description on how this antenna was developed on the web site http://AmateurRadioStore.com and here is some of that content:
"To develop the Alpha 6-160 meter J-Pole Jr Antenna we used an Antenna Analyzer that simultaneously shows the SWRs of 5 bands. The inspiration behind the J-Pole Jr from Alpha Antenna came from a combination of antenna designs, namely the J-Pole and Zepp. Along with a matching network technology, which we attached the specially selected outdoor rated wire to, we then spent over three months cutting and trimming the wiring till we achieved a resonant antenna design on 6, 10, 15, 20, & 40 Meters and a tunable resonant pattern on 80 & 160 Meters. We adopted the J-Pole name for this antenna because the result of our design were two separate lengths of wire that are parallel to each other. We also learned the spacing between the wiring was critical in their respective sheaths, as well as the size & number of the strands of the wire within each sheath. From the Zepp Antenna we borrowed the end-fed type design, which is also similar to the end-fed
design of a standard J-Pole antenna. Although significant, the wiring is by no means the only factor in matching the antenna. The matching box allows for the antenna to be fed with 50 ohm coax at the antenna. This makes for an important design characteristic when feeding a tuner, as it keeps the RF voltages low at the base feed point."

I visited my local TSC store and picked up a bag of 10 "corner insulators" for an electric fence. Cost was $2.50. A quarter mile of 17 gauge aluminum wire was about $25.

The insulators were a little lighter weight than those I bought for another antenna from one of the ham shops. They are also bright yellow. A little black mat spray paint will make them less visible and provide more protection from the Arizona sun..

TSC has always been a favorite place!

Here in these suburbs it is actually hard to find electric fence wire. Hardware stores don't sell it, and there are no farm supply stores nearby. (Surely they must be out there, just very difficult to find, and a bit of a hike - er, drive to get to.) If I needed to get some, I might have to do it by mail-order from the midwest.

I'm told that a cheap source for copper wire, if you don't mind solid, is a motor repair shop, where they re-wind motors. They might have leftovers from big spools that they can't use.

And that suggests one can get copper wire for free by salvaging old fan motors, or any other unwanted motors you have laying around.

Andy

I looked at the larger black insulators. They were about twice the size of the ones I bought. I thought that perhaps the smaller ones wouldn't be as visible since I live in a HOA area.

For those that don't have a TSC store I had researched and found the same insulators at Home Depot and Lowes. I did not check Ace or TrueValue.

While I'm going to use 14 gauge stranded and insulated wire for an OCF I have used copper-clad welding wire with good results.

30984. Re: [ham-antennas] Coax Feed

Yahoo group: ham-antennas (2014)
Date: 2014-01-17 06:00:20 UTC
From: Andy
Topic: 30856 Message: 30984

Going back to a question from a few days ago ...

"Somewhere I read that coax lenght could be counter productive on certain freq. (i.e. one should avoid running 30 meter lenght of coax to a 10 meg antenna)."

I can think of 4 reasons where coax length matters with antennas:

(1) The coax is a "phasing line" in the antenna or array. The antenna probably came with that coax, or someone made them to connect two or more antennas together. In that case, do not cut the lengths shorter. They need to be that length, whatever it is.

(2) RF loss. The longer the coax, the more signal you lose, and this gets worse as the frequency goes up. It also gets worse if the SWR on the coax is up there. According to this rule (alone), make your coax as short as you can.

(But there are some antennas that specify a minimum coax length, to get enough loss to make the SWR look good!)

(3) Re-radiation. The presence of coax in the near-field of an antenna can become a parasitic element that messes with the antenna's pattern. Resonant lengths near even or odd multiples 1/2 wavelength, at any frequency you use, are best avoided. Do not use the VF (velocity factor) in this calculation because you are looking at the coax from outside, like a solid wire. Note: While this can be a concern, it is not a biggie, and can be avoided by running the coax at right angles away from the antenna.

The same consideration also affects antennas that should use a balun but don't have one. When the feedline length is the right length to be resonant, it can amplify the effects of RF on the outside of the coax.

(4) Getting a certain impedance at the shack end, when the SWR on the coax is NOT low. More on that follows:

When the SWR is already low, it doesn't make much difference how long the coax is (except for (1), (2), or (3) above). The input impedance will look close to 50 ohms whether it's 1/4 or 1/2 wavelength or anywhere between.

When the SWR is not low, sometimes you want to see the same impedance at the shack end, that exists at the antenna. To make that happen, the effective length, taking VF into account, needs to be 1/2 wavelength or any (even or odd) multiple ... so you would want to avoid odd multiples of 1/4 wavelength.

Personally, I'm not sure why one would need to do this. But I'm sure there are situations where it helps. Let's say you have a large loop and its

resonant feedpoint impedance at some frequency is 180 ohms. You can bring that 180 ohms into the shack by using 1/2 wavelength of coax, or a multiple. OTOH, if you used 1/4 wavelength of coax, it would be transformed down to 13.9 ohms. Both are the same SWR (I'm assuming the use of very low loss coax here). Now it may be that your shack-end ATU or rig can handle 180 ohms easier than it can handle 13.8 ohms, even though both are the same SWR; so in this case it makes sense to use something near 1/2 wavelength, and avoid 1/4 wavelength.

So, considering only case (4), IF you need to see roughly the same impedance as exists at the antenna, use 1/2 wavelength or an integer multiple, and remember to incorporate the velocity factor of the coax when you make that calculation.

But there's no guarantee that the antenna's feedpoint impedance (with a high SWR) is necessarily the one you need to see in the shack. It might be that things work better if the coax length is 1/4 wavelength long, or an odd multiple. Or something else.

AFAIK, a short coax (< 1/4 wavelength) is rarely ever a problem.

30987. Turbo TunerII Screwdriver Antenna Controller Source

Yahoo group: ham-antennas (2014)
Date: 2014-01-17 12:40:17 UTC
From: WD8ARZ
Topic: 30607 Message: 30987

Have been using the original Turbo Tuner with my TS-480HX 200 watt hf radio for about six years now. Zero problems. What I absolutely love about it is the simplicity of operation and how much it improves driver safety and getting your screwdriver antenna to its lowest swr.

All I do is select the band and frequency I want to operate on, press the PF key on the Display panel of Hand Mic that is programmed for the Tune function, and just drive. The rig goes into transmit, and the Turbo Tuner takes over. When it has adjusted the Screwdriver antenna for lowest SWR it sends out a CW dah dit dah (K) and returns the radio to receive mode. At that point I know it is ok to transmit. Single push button operation couldnt be any simpler.

To aid mobile driving, I have programmed my TS-480HX memories for frequencies of interest for all ham bands. From the hand mic I can step up and down through those memories looking for chats of interest to listen to while I keep my eyes on the road driving, or to find a clear one to call on. Those memories are tunable, so it is also easy to manually dial around the band and not be limited to the memory frequency. Again while keeping my eyes on the road.

Because the screwdriver antenna can have different capacity hats and whip lengths that can be used for it, the swr for a frequency will be different for each antenna combination, especially 40 - 160 meters. Thus a memory antenna tuner would not be as good a choice for me. Thus I prefer a screwdriver antenna tuner that finds the lowest swr each time it is activated regardless of frequency and antenna configuration. is always going to configure the antenna correctly each time.

Here is the link to the Turbo Tuner II by GigaParts:
http://www.gigaparts.com/Product-Lines/?search=turbo+tuner&sc=29&Submit2.x=0&Submit2.y=0
Each version of the Turbo TunerII can be clicked on for more details.

GigaParts is the distributor. Here is the link to Tennatronix who makes em and has the manuals for download:
http://tennatronix.com/home.html

Note, these links have nothing to do with the original Turbo Tuner whose author has died. Same updated product, but not same company.

I was in a HOA in houston and made my dipole from 1/16" galvanize lift cable and did not use end insulators . hid the centre insulator and twinlead behind a tree and it was never spotted . after it was up for a while the wire turned a dull gray colour and was almost invisible against the sky . my 10 metre vertical was visible and when the HOA asked I told them it was a lightning rod .

Topic: 30989 Message: 30989

My wife and I recently bought our first house and I am looking at putting up some antennas. At our previous location I had several LARGE oaks to suspend things from. At the new location I don't have any trees to act as supports. So, I have an idea but I wanted to run it by you guys first and see what you think.

My plan is to support a dual or tri band vertical (50/144/440) and a 10 & 20 meter dipole from the following:

I was going to get two 10' sections of chain link top rail and weld/bolt/sleeve them together. For the base, I was thinking of taking the bottom 1' of a 55 gallon plastic barrel and mounting the pole in that with concrete. The pole would be right next to the house, and where it passes the roof line/fascia it will be secured. I was also thinking of guying the top if necessary. The support lines for the dipoles could play into that quite easily.

Just wondering if you guys think this is a solid & inexpensive plan, or does it sound a little too much like hillbilly engineering?

Thanks,
Albert

My first thought would be to use the whole 55 Gallon drum filled with rocks/concrete and forget the guys. But you might need some of Pop-eyes spinach to move it. If filled with rocks not concreted together they would be removable.

Anybody used the poles from wind-surf boards as a support?

Cheers
Will

Yepp ... i have a surf pole in one of my trees (to have the antenna free from the branches) ...

... what about using the house height??

You only need a 6m pole to get to 15m height if your house already is 10m high (also doing that here)

From: Richard Schmuke
Topic: 30989 Message: 30992

Here is a inexpensive plan but it is from a hillbilly. It is good for 20 to 30 ft. This can also be used for a rotor and hex-beam in the future.

http://s1102.photobucket.com/user/KD0ZZ/media/Tilt2.jpg.html

Look at the sketch and then there are a few pictures of it in the album. You will also find plans and pictures of a 40ft support that holds up my rotor, beam, large loop and 160/80 dipole in my album. Sorry I don’t have any citified plans but hillbilly engineering is all I know.

This could be made smaller or larger according to your layout and room.

Rich, Kd0zz

30993. Best balun manufacturer

Yahoo group: ham-antennas (2014)
Date: 2014-01-18 21:57:21 UTC
From: <yg@...>
Topic: 30993 Message: 30993

Yup, I did Google and searched this forum and got lots of related hits but not anything that could be called a consensus..

Just wondering if there is any kind of a consensus for the best balun manufacturer for legal-limit 1:1 and 4:1 current baluns. Balun Designs and DX Engineering seem to get good reports, and a few others not so much.

This will be used with an inverted V cut to 160M and fed with window line. Another one will be used with a slightly-shorter-than-160M inverted V (ran out of room) also fed with window line. The window line runs to the balun mounted outside the shack window, then a short length of coax to an LDG 1000-watt tuner, then to my 700-watt station. Both antennas will be used 160-10 plus MARS and CAP frequencies, and relatively seldom will they be run at resonance points.

Any recommendations gratefully accepted.

Actually Rich, in some ways, hillbilly engineering is the best....

And a question for you:
The pipe detailed in your drawings, is it just regular schedule 40 pipe from the hardware store? Also, on the "small" version of your tilt up tower, I see that the lower section is 1.5", but what is the diameter of the upper section?

Thanks,
Albert

Me too - had a 4:1 1KW DXE balun, then bought the Balun Designs 4:1 3KW unit. Put both of 'em on the end of my AIM-4170C analyzer. No doubt about it, the Balun Designs unit was flatter across the 1.8 - 30 MHz range.

http://s1102.photobucket.com/user/KD0ZZ/media/Tilt2.jpg.html

Well, yes , no and mebey. The smaller one it was built 30 years ago and I went to a scrap yard and bought two sections of pipe that telescoped together. One was a gas pipe and had the yellow plastic coating on it as I recall. I think they would be called 1 1/2” and 1 1/4. Note I did not buy it from a hardware store because some of that pipe is not as weldable as regular steel pipe unless you are careful and use 7018 rod and I am not a good welder. Being standard S40 it was 21ft long so I paid the man an extra dollar and he cut about 5 ft off the 21 and that made the shorter vertical part. It was made with holes in the base so it could be mounted on studs and that made it easy to set it vertical also when I got ready to move it was easy to take it all down. When I retired and moved out where I have no rules and regulations I made the larger one. I keep the shorter one for testing. The last tilting unit I made was done with treated lumber and mounted on a treated 4x4 in concrete. Picture of the assemble in work can be seen at. Note: All work is feline inspected.

http://s1102.photobucket.com/user/KD0ZZ/media/Multi%20Band%20Vert/MBVert005_zps78008c01.jpg.html

Please disregard the antenna being built it this album , it is just one of my many that was not a great success but now the tilt unit is being used for a raised feed point 40M vertical that works great.

The larger steel tilt design required no welding just drilling a couple of holes and being in concrete I don’t plan on removing it. After I am a silent key it is someone else’s problem. If I had to remake the larger one I would use 2 full lengths of 2x3 steel tubing (21ft) to raise the pivot point higher. I tilt it now with a come-a-long at the base but with the rotor on top and a beam it gets a little heavy for a 69 year man. If you look at the picture of the whole assembly you can get a idea of the leverage as it is tilted. The picture shows a 3 element 15M beam. It now has a Hex beam.

My wife and I recently bought our first house and I am looking at putting up some antennas. At our previous location I had several LARGE oaks to suspend things from. At the new location I don't have any trees to act as supports. So, I have an idea but I wanted to run it by you guys first and see what you think.

My plan is to support a dual or tri band vertical (50/144/440) and a 10 & 20 meter dipole from the following:

I was going to get two 10' sections of chain link top rail and weld/bolt/sleeve them together. For the base, I was thinking of taking the bottom 1' of a 55 gallon plastic barrel and mounting the pole in that with concrete. The pole would be right next to the house, and where it passes the roof line/fascia it will be secured. I was also thinking of guying the top if necessary. The support lines for the dipoles could play into that quite easily.

Just wondering if you guys think this is a solid & inexpensive plan, or does it sound a little too much like hillbilly engineering?

Thanks,
Albert

Anybody have any suggesions for a high-gain 2-meter omnidirectional vertical, something like the Diamond or Comet high-gain collinears of around 7+ dB gain, but will handle at least 500 watts of power on FM?

Something like the Diamond F-23H would almost work except that it's only rated for 350 watts and I could use just a bit more.

Thanks...

Goodness. That's a whole lot of learning to do! I hope you are listening to your doctors, and are getting enough rest.

A wire antenna will be your friend...as will some local hams to help get it up in some trees. (That will be inexpensive compared to buying things off the internet....)

What part of the country are you in?

A friend just put up an 80 meter doublet, fed by open wire (about 600 ohm --- all hand made) - That might be a bit much for you to do, but he is getting incredbile results.. (and has some nice 80' tall trees behind his house to make that possible...) - works all bands his radios work with an external tuner..(balanced feedline helps with the efficiency.)

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Can anyone direct me on how to correct SWR on 40 and 80 meters?

I have checked SWR repeatedly with antenna analyser and 40 is resonant around 6.600 and 80 is around 3.000.

I am not sure if I should lengthen or shorten that section or start messing with the capacitance spokes.

Any advice would be appreciated

Looks like you need to lengthen nothing , so go from there . What study material did you use ? Chuck Wq5B

Just thinking here, and unless my Ohm's law is way out of line here. or anything else why it shouldn't work?

OK the average LED runs pretty good at what 1.5 to 2 volts right?

In a 50 Ohm system that comes out to only 0.04 watts to get that voltage.

Could we make an illuminated WATT / SWR meter by tapping into the RF?

I mean with only 0.04 watts of drive we already have enough voltage to light the LED.

Add in a regulator or something that will not allow any higher voltage to go to the LED even when running Legal limit, 275 volts.

This way we could have an illuminated meter without having batteries or external power supply needed.

Thoughts?

Possible to be sure ..... but the voltages involved can be quite extreme
especially under high SWR. making the over voltage regulator circuit a
bit of a challenge

yes and no? the Led would light on only one direction, and since it is a kazillion times faster than 50 or 60 cycle "Power" you'd never ever see the flicker true? The flicker from the modulation would be far more obvious than the flicker from the AC Freq.

Wind a small coil on the outside of the coax to avoid having to build high voltage circuits and the attendant hazards then rectify it to dc enough to give voltage to light a led.

If your antenna is made correctly there shouldn't be any voltage there.
There should never be anything on the outside of the coax.

From: Stan Labinsky Jr.
Topic: 31012 Message: 31023

SigThat’s why the rectify and filter approach is to be desired. A... say ten or so MFd cap would hold enough of a charge to smooth out any modulation affects. However, all bets would be off if you were monitoring SSB.

One other reason to not connect directly to the pickup... coil, or whatever is used, is that LED’s reverse voltage is not too awfully high.
You might see a situation where the forward current flow is OK but forcing the junction on in the reverse might make it warm enough to kill the lamp.
That’s why you might see a 1N400-whatever in series with the lamp wired across AC, to protect its junction from reverse punch-through.

Stan

I use a LDG YT-100 tuner and it tunes the Alpha MOTO on all the bands its' manufacturer states. It works really well on 6 through 20 meters and surprisingly well on 40 meters. On 80 meters I've only had 2 QSOs and they were in my same State, but I don't use that band much.

I mounted it on the lip of my front fender where the hood comes and hides the bolts on the Alpha Jam Mount, all of which I bought from http://AmateurRadioStore.com (tuner, antenna, & mount).

I'm new to HF. However, I, too, use an Alpha MOTO Sr. Although, I have a 102" whip attached to mine and use the LDG AT200PROII Tuner with my Icom IC-7000. It tunes 160-6 meters without any problems. I use this setup as my backup for my Micom radio for the Civil Air Patrol, not that we have anything in the 6 meter band, but we do work 1.6-30 MHz. I currently have one antenna sticking straight up for DXing. I plan to add a second one on the other side of my van and fold it down & toward the front for NVIS work and switch between the two when needed.

Sent from my iPhone...Please forgive me for any possible typos. :-)

Thank you Joe,

The antenna is ground mounted, I have adjusted all the other bands almost perfectly.

I have adjusted "E" to no avail starting at the recommended 22"

I will try removing 1 spoke from 40 just to see where that goes,
at least this will give me some idea.

be careful here, lengthening under a loading coil - which is what a trap is if not on its resonant freq. - can actually raise resonant freq on lower bands. the higher the coil is placed electrically it becomes less effective. There was an artical in QST in the 70's - maybe by W2FMI, on a 14AVQ if I recall correctly that discussed this.

OK, my question is to all who like this antenna...why pay $200 for an antenna that still has to have a tuner to work all bands? I can do that with a much less expensive antenna. What an I missing?

I'm new to HF. However, I, too, use an Alpha MOTO Sr. Although, I have a 102" whip attached to mine and use the LDG AT200PROII Tuner with my Icom IC-7000. It tunes 160-6 meters without any problems. I use this setup as my backup for my Micom radio for the Civil Air Patrol, not that we have anything in the 6 meter band, but we do work 1.6-30 MHz. I currently have one antenna sticking straight up for DXing. I plan to add a second one on the other side of my van and fold it down & toward the front for NVIS work and switch between the two when needed.

Can you work all bands at 70 miles per hour or 112 km. Its like using a screwdriver antenna without any moving parts. If you do what antenna is it.

Let me start off by apologizing if this reply does not get in the digest in the correct spot. The Alpha MOTO is designed as a multi-band antenna. You do not need to use a tuner with it. I choose to use a tuner because it reassures me that I'm getting the best SWR and the best power output that I can. In addition, it does allow the tuning of the 160 meter band, which the Alpha is not guaranteed to do with the supplied whip. I think, just off the top of my head, it is 6 to 80 meters, depending on the length of the whip you are using. There is a video on their website, that demonstrates the ease of use of the Alpha. https://amateurradiostore.com/all-alpha-antennas-c-2/mobile-alpha-moto-sr-easily-tune-680-meters-500-watts-p-164?zenid=uh29ps9l6k50aifu4q8mvbi1t0

I like the Alpha a lot better than the Littlle Tarheel. So, if anyone is interested, I'm selling a Little Tarhel with Super tuner with cable for the Icom IC-7000. I've had it less than a month. 73 KB0CAP

The cheapest decent mobile antenna is the Alpha MOTO. Consider the options; Hamsticks used to be considered the least expensive way to get on the air, but you'll pay $20 per band. The MOTO will hand you 10 bands, which is $200 worth of Hamsticks. Plus you don't have to stop your car every time you want to change bands. Look around some more on how people are using their Hamsticks and you'll see they are using antenna tuners to get a little more band coverage out of them as a Hamstick give you about 15% to 20% of usable bandwidth for each band. That sounds like more of a ripoff now that I've actually typed and re-read it! The Hamstick is also around 6 1/2 feet long. I have owned and used Hamsticks and they hit nearly every tree out there and I can't pull into my garage, not the case with the MOTO at only 62 inches long. Hamsticks have their place, and I've found that place is on my boat, where I have a 9 position band switch with seven coaxial cables running to 9 independently mounted Hamsticks. After all, I'd already spent he money on them and couldn't see them go to waste. I'd have not bought them if I had to start over though, but then again, the MOTO wasn't available till 4 years ago. Got another idea of a cheaper antenna that'll give me all the bands? Please let me know what it is! I'd love to try it.

I have an old 14AVQ. I have found that the dimensions/lengths of tubes vary greatly between different vintages of the model. I had to match up the pn's of the traps with an older manual. The current one at hygain/mfj is completely different. Then after all that I discover I have the tubes for the roof mounted version and I want to ground mount it!

I used a "milwhip" with fc1000 tuner ... worked all bands and I could drive
200mph with it (if my car would be that fast) ... tested with 200+ km/h

Military whip antenna was cheap from a flewmarket

Interesting question, Joe. There are simple circuits that light up an LED in the presence of RF power, even give you a relative indication of power level (or SWR level) from the LED's brightness. I see them built into homebrew QRP antenna tuners. You switch them in to tune the antenna/tuner, then switch them out. Often that's because the SWR bridge is a simple resistor bridge not a directional coupler, and it uses too much RF power to get a usable SWR indication.

I think it's not a great idea to have the LED directly across the RF terminals. Yes it's a diode, but a bad one for RF. Probably too slow, and probably quite a lot of junction capacitance, and I don't know what else ... not the kind of thing you want to hang across an RF line. So you probably want to rectify first with a good fast RF diode, then think about applying DC to the LED.

The act of hanging something across RF that actively rectifies it, even if it only steals a little of the RF, will generate harmonics, and that's not good. If you can make the "device hung across the RF" look like a linear resistance, and a very large resistance, that would be best.

So what do you want your LED to show? Just an RF presence indicator, that gets brighter or dimmer? Or a series of LEDs in a bargraph display? Or a complete digital readout, showing Pout and SWR?

There are some nifty voltage regulator ICs that work on much less voltage than a dead AA battery, and step it up to something useful. So there are possibilities.

Regards,
Andy

OK, enough of this new-fangled stuff ... get an old NE-2 Neon Lamp and stick
a loop of wire on it !!

As an added bonus, if you have parasitics, you can tell the frequency region
by the color.

A whip of any reasonable length and a tuner does the same thing. A friend of mine does well with an 80M hamstick and his tuner for a lot less money. Is it perfect? Show me one that is! I just wonder about a $200 antenna that still needs a tuner to work...that equates to a $400+ antenna system to me. I have a military whip and mount for about $50 that works with my SGC tuner. It's longer than 62 inches, but works well. I admire many different solutions, just trying to figure out if this is $200 worth of snake oil or a real benefit. I am viewing this with an open mind, and wouldn't mind trying it actually. Just have limited $$$.

I understand Bill. I have a 20M Sierra Slim (hamstick) that does not need a tuner. In fact my 10M to 20 meter ones do not need a tuner. My original question to you was can you change your hamsticks out without stopping your vehicle. That is not going to happen. You are mentioning just one frequency. He was mentioning from 80 M to 6 M's.

I primarily talk on 20 meters but if I want to talk on 10 meters then I have to pull over and get out and change my hamstick. Not much fun and $200 is far cheaper than going to a screwdriver antenna.

I know there are a lot of hams out there that can do the same with some homebrewed stuff but I no longer can homebrew anything do to my tremors. If I can scrape $200 together I would buy one.

Maybe you missed one item, or overlooked it. My friend uses the 80M stick and tuner for all band work. That is a cheaper alternative that I see. Better? dunno. Does work, however. All mobile work in the HF region is iffy and at times pretty sketchy anyway. Still, I like seeing other possibilities, even if they might not work for me. Heck, at the base I use a B&W folded dipole. It works for me, I was kind of thinking that this MOTO was a dummy load type of thing also over it's reported bandwidth. Getting signals out & back are still successes, no matter what you use!

OK, MSRP of $199 & on sale for less.
MOBILE - Alpha MOTO Sr Easily Tune 6-80 Meters 500 WattsAlpha MOTO Sr Mobile 6-80 Meter QRP - 500 Watt Antenna All Alpha Antenna systems are handmade & built to order at our shop in Greenwood, MO. We...$199.00 $139.00
Save: 30% off

Add:

It still makes them think that it is a $200 antenna.... Still need a tuner according to them to go below 40M.
==========
OVERALL OPERATION - The entire antenna system is specifically designed for 6 through 40 Meter mobile operations. In addition to allowing you to tune 6-40 meters, it will also allow you to tune 60-80 Meters when properly grounded. The optional Alpha Jam Mount will give you a well grounded installation for full use of 6-40 meters and enable you to tune these bands plus 60-80 meters with an automatic or manual antenna tuner.

TUNING THE MOTO - All native SWRs, when necessesary, can be tuned with an antenna tuner, because they are between 1.4:1 on the higher bands to 5.4:1 on the lower bands.
==========
Therein is the reason I said it was actually more expensive, since for "all band" it needs a separate tuner!

Subject: [ham-antennas] RE: mobile hf antenna

The cheapest decent mobile antenna is the Alpha MOTO. Consider the options; Hamsticks used to be considered the least expensive way to get on the air, but you'll pay $20 per band. The MOTO will hand you 10 bands, which is $200 worth of Hamsticks. Plus you don't have to stop your car every time you want to change bands. Look around some more on how people are using their Hamsticks and you'll see they are using antenna tuners to get a little more band coverage out of them as a Hamstick give you about 15% to 20% of usable bandwidth for each band. That sounds like more of a ripoff now that I've actually typed and re-read it! The Hamstick is also around 6 1/2 feet long. I have owned and used Hamsticks and they hit nearly every tree out there and I can't pull into my garage, not the case with the MOTO at only 62 inches long. Hamsticks have their place, and I've found that place is on my boat, where I have a 9 position band switch with seven coaxial cables running to 9 independently mounted Hamsticks. After all, I'd already spent he money on them and couldn't see them go to waste. I'd have not bought them if I had to start over though, but then again, the MOTO wasn't available till 4 years ago. Got another idea of a cheaper antenna that'll give me all the bands? Please let me know what it is! I'd love to try it.

That's his claim. I know how active he is on 20, 40 & 80, so I believe him. I have a military whip (multiple sections) and an SGC, as well as a Hi-Q for a different vehicle. I guess it just depends on what you want to use...maybe flavor of the month? Remember the big pull for the G5RV and then the Zepps? Now I'd lean toward a 160M horizontal loop (I have the space). It's all fun and interesting, huh?

Maybe you missed one item, or overlooked it. My friend uses the 80M stick and tuner for all band work. That is a cheaper alternative that I see. Better? dunno. Does work, however. All mobile work in the HF region is iffy and at times pretty sketchy anyway. Still, I like seeing other possibilities, even if they might not work for me. Heck, at the base I use a B&W folded dipole. It works for me, I was kind of thinking that this MOTO was a dummy load type of thing also over it's reported bandwidth. Getting signals out & back are still successes, no matter what you use!

I understand Bill. I have a 20M Sierra Slim (hamstick) that does not need a tuner. In fact my 10M to 20 meter ones do not need a tuner. My original question to you was can you change your hamsticks out without stopping your vehicle. That is not going to happen. You are

mentioning just one frequency. He was mentioning from 80 M to 6 M’s.

I primarily talk on 20 meters but if I want to talk on 10 meters then I have to pull over and get out and change my hamstick. Not much fun and $200 is far cheaper than going to a screwdriver antenna.

I know there are a lot of hams out there that can do the same with some homebrewed stuff but I no longer can homebrew anything do to my tremors. If I can scrape $200 together I would buy one.

Pulled the antenna down a few times yesterday,
Took 1 spoke off of 40 meter, resonance went from 6.750 to 7.000.

Removed 1 spoke from 80 meters, not enough so I removed a second spoke and resonance went from 3.000 to 4.200, too far/toomuch.

31049. Mobile HF Antenna - MOBILE - Alpha MOTO Sr Easily Tune 6-80 Meters 500 Watts

Yahoo group: ham-antennas (2014)
Date: 2014-01-22 14:04:15 UTC
From: WD8ARZ
Topic: 30607 Message: 31049

Hello Bill, another HiQ Screwdriver user here too.

Have considered a second hf antenna on my Trail Blazer. That way I could use it for say APRS on HF, while continuing to operate voice on the HiQ. Being ale to monitor on two hf frequencies full time would have some uses for me. Would of course have to protect the receiver front ends from harmonics and the fundamental frequency accidental tune in .... hi .... and the tuning effect of one antenna on the other, etc Looks like the Alpha MOTO Sr would mount off the front of the Trail Blazer very easily, and place some distance to the HiQ mounted on the rear. Have used such arrangement in the past, plus a center roof mount on a station wagon.

Have read over the eHamnet reviews, and as usual the reports of 'how great' it works on 10-20 and how much DX was worked, is not very useful to me. Even for 40 meters when the band is open. Heck, when 10 - 40 are open, you can work the world on a wet noodle and five watts. That goes for all hf mobile antenna reviews regardless of brand. Love operating on those bands hf mobile, and I do it a lot. Heck, even discovered a group of AM hams operating on 15 meters on my last trip couple weeks ago while traveling from TN to Indiana .... hi hi

For me, I must be able to have performance on 80 - 160 meters. That is where the Q of an antenna and its radiation efficiency, start to sort out the actual performance of one hf mobile antenna to another. Certainty the high quality of materials, design and attention to detail go along way too, and this product appears to be one of those.

To be clear, I am Not knocking this antenna, in fact I am very interested in it even though I do have a better mobile hf antenna now (for 40 - 160 where the differences turn up). It is not even about a 'shoot out' of this antenna against other brands - there are lots of problems with those evaluations too by the way .... hi

Like the web site, good information provided, and the owner sounds like a great guy I would enjoy doing business with ... and some day after other priorities are taken care of, I will pursue a possible purchase. Based on the SWR performance as detailed in the user manual page 5, I would say a tuner is needed to help keep the transmitter power from reducing. http://alphaantenna.com/pdf/Alpha_Antenna_MOTO_User_Guide.pdf - That adds to the total cost factor.

For my only HF mobile antenna, I will stay with the HiQ (plan on getting another the 6/160 for better efficiency yet on 160), but as an additional or back up antenna, or just for 10-20, yep, looks like this

Alpha MOTO Sr would be a good one to try out.

Rich,

I viewed your plan for the tilt up mast. Would really like to try building one. So it's good for 30 ft. from what you stated? I didn't see any in your pictures but does it have to be guyed? I have a Mosley TA33jr that I really need to get up in the air. I was hoping to buy a tower but circumstances say this wont happen anytime soon. But this project I could swing. The MOsley weighs about 25 lbs. Not sure about the rotor. We are very limited on what we can buy here. Any suggestions on where one might find the tubing and pipe? We have access to Lowes and Home Depot. But they are over an hour away.

Thanks
MArk/W7MCP

31051. HF Mobile - Links Of Interest

Yahoo group: ham-antennas (2014)
Date: 2014-01-22 17:06:02 UTC
From: WD8ARZ
Topic: 30607 Message: 31051

For those interested in HF Mobile operation, there is an interesting discussion going on that your welcome to participate in.

Regards and 73 from Bill - WD8ARZ
==========
Over the last few months a lot of different topics have been covered about HF Mobile.

Many of my comments have been rather specific and detailed about equipment, antenna's, installation and operation.

Am wondering now if there is not some value to getting back to the basics. After all, we don't normally launch into various aspects of our hobby with full blown systems. Generally I suppose we start out simple, using what we have, make, modify, can borrow or buy on the cheap.

With that in mind, I would like to propose that those who are already into hf mobile, encourage, support and aid others to join in, but to focus on just the basics. What about encourage those that have never done hf mobile, to give it a try at the most minimum level using what they already have, or can get their hands on.

Point being?

Unless the HF Mobile Bug bites one, no need to go the extra time and expense. However note that the effort for the most basic system still requires most of what better systems can grow out of this initial exploring effort. Such as:

* Power take off location, and safety
* Antenna to use, and safety
* How and where to mount antenna
* Where to place mobile radio and safety

In other words, what is the minimum it takes to get on the air from a hf mobile that can drive at high way speeds, using what is at hand or cheaply available.

If and when the bug then really takes hold, the HF Mobile System can grow as time, budget and equipment becomes available to enhance the operation. Not to mention discovering how useful HF Mobile Operation can be to an individual operator, but also as a resource to support other aspects of amateur radio activities.

One resource I can share here, is the various other reflectors where this topic has come up:

I don’t know about your location but around here most people live in houses with a basement. The basements have a “I” beam down the center and steel post, for support steel angle above the basement windows to provide support for load bearing walls so if you have homes there is a steel shop close by. Check the net for location of steel shops and also a scrap yard is cheaper. Lowes and Home Depot do not carry standard steel pipe. They do carry 10 sections of rigid conduit.

I had a 3 element 15 meter beam and a CD45 rotor on it for several years with no guy wires. When I went to 40 ft plus with the other design and on a open hill top I added guy wires. Here is a first install picture, before guy wires.

The cheapest decent mobile antenna is the Alpha MOTO. Consider the options; Hamsticks used to be considered the least expensive way to get on the air, but you'll pay $20 per band. The MOTO will hand you 10 bands, which is $200 worth of Hamsticks. Plus you don't have to stop your car every time you want to change bands. Look around some more on how people are using their Hamsticks and you'll see they are using antenna tuners to get a little more band coverage out of them as a Hamstick give you about 15% to 20% of usable bandwidth for each band. That sounds like more of a ripoff now that I've actually typed and re-read it! The Hamstick is also around 6 1/2 feet long. I have owned and used Hamsticks and they hit nearly every tree out there and I can't pull into my garage, not the case with the MOTO at only 62 inches long. Hamsticks have their place, and I've found that place is on my boat, where I have a 9 position band switch with seven coaxial cables running to 9 independently mounted Hamsticks. After all, I'd already spent he money on them and couldn't see them go to waste. I'd have not bought them if I had to start over though, but then again, the MOTO wasn't available till 4 years ago. Got another idea of a cheaper antenna that'll give me all the bands? Please let me know what it is! I'd love to try it.

31058. Mobile HF Antenna - Loop

Yahoo group: ham-antennas (2014)
Date: 2014-01-22 22:30:50 UTC
From: WD8ARZ
Topic: 30607 Message: 31058

Thats interesting. Have heard about some hf mobile loops for vehicles that have the roof room. Image RV's would like em too.

Are you looking to make one of your own? What vehicle are you looking to put it on?

If I remember right, that gives some NVIS performance too doesnt it?

A strong dipole would be interesting. Sounds like a lot of coil loading. What frequency range were you looking to get out of it on your mobile?

Let us know how this works out for you.

Topic: 30989 Message: 31059

Hi there Rich,

I have the Mosley T33 jr atop a 40 foot mast. I call it a tower but its round. No guying needed but I have the Yaesu G800DXA rotor or rotator. Its more than enough for my antenna. The guys on field day used a rope around the toper to turn the beam but I would not recommend that for full time, especially if you have a lot of wind. To start with I bought a really cheap rotor that worked very well but the guy that put it up there did not use a fat enough pole and it was turning on the pole when the wind blew. I'm very happy with my setup now.

Subject: [ham-antennas] Re: support pole/tower construction idea

Rich,

I viewed your plan for the tilt up mast. Would really like to try building one. So it's good for 30 ft. from what you stated? I didn't see any in your pictures but does it have to be guyed? I have a Mosley TA33jr that I really need to get up in the air. I was hoping to buy a tower but circumstances say this wont happen anytime soon. But this project I could swing. The MOsley weighs about 25 lbs. Not sure about the rotor. We are very limited on what we can buy here. Any suggestions on where one might find the tubing and pipe? We have access to Lowes and Home Depot. But they are over an hour away.

Thanks
MArk/W7MCP

Date: 2014-01-22 22:45:31 UTC
From: dean
Topic: 30607 Message: 31060

Well I only do NVIS in my vehicle when its parked. I have a small 01 Golf TDI. I have my antenna wire connected to the antenna mount and I first made it for 40 meters. I put a spade lug on the end of the antenna and then make it to 80 meters. My car is the other side of the dipole. I put it up about 12 to 15 feet mostly so people don’t touch the antenna while I’m transmitting, I have to remember good safety. If I want to talk on 40 meters then I just connect the two antennas together. That’s what the spade lug is for. I used to like in Fresno, CA and talked to San Francisco. Not too shabby.

I’m not looking for a loop antenna for my car. I would like one for my house but I don’t’ have the $$$ to put one up. I could do a nice 160 here. It has absolutely nothing to do with mobile HF antennas, but if it really bothers you just delete the message.

From: WD8ARZ
Topic: 30607 Message: 31061

Now thats a good point. Not only mobile hf antennas for the mobile while in motion, but how to improve the mobile antenna options for operation while parked.

Thats a nice next step to be prepared for. I keep a charging power supply for the extra battery in my vehicle used just for ham gear, extension power cord, and a couple rolls of one hundred foot wire, and a auto tuner to use when parked at family and friends homes when I travel. Can still use the screw driver antenna on the mobile, but why not go for the better antenna when one can eh?

Now that I am retired, I obviously dont drive as much. But I do travel out of state often enough that I frequently leave my mobile gear installed in the Trail Blazer. It is parked in the garage at my home a lot, and not driven as much. Some times I put the charger on the spare battery for the ham gear, put the tuner on the hf rig, and plug in the outside ham antenna. Now the mobile in this cold weather will operate just as if it was in my house as a base hf station.

As the earth turns on it's axis...Really we are all talking about great possibilities. Most of the mobile antennas come from ideas used on terra firma. Loops just happen to be my direction of study for now. Smaller ones like those coming out of the Middle East for Land Rovers et. al. have my attention for band usage. They fold down for travel and up for use. Lots more $$$ than Alpha's package, darn it. I'll stay with my whips, until these others can match my payout abilities. Still interesting.

Speaking of loops for mobile. I saw a prototype of an Alpha Loop Sr and it could be mounted mobile (or base)! It is (will be) a MLA (magnetic loop antenna) that does handle 100 watts and operates on the same bands as the Alpha Loop Jr. The guy from Alpha showed me how it might be able to work on 80 meters also. Problem was that he also said that it wouldn't likely be available for another 18 months and that it's a manually tuned system, although I imagine that it'd be easy enough to add a remote on it.

Subject: RE: [ham-antennas] RE: mobile hf antenna???

Speaking of loops for mobile. I saw a prototype of an Alpha Loop Sr and it could be mounted mobile (or base)! It is (will be) a MLA (magnetic loop antenna) that does handle 100 watts and operates on the same bands as the Alpha Loop Jr. The guy from Alpha showed me how it might be able to work on 80 meters also. Problem was that he also said that it wouldn't likely be available for another 18 months and that it's a manually tuned system, although I imagine that it'd be easy enough to add a remote on it.

I have had a very positive experience with my mobile magloop and a 10 watt KX3 QRP transceiver. If interested, details are on my QRZ page (K4HKX). Scroll down to the mobile magloop section. Anecdotal reports are pretty much worthless, but interesting nonetheless. I recently enjoyed a 55 report from the Ukraine on 40 meters SSB while in motion, and I have worked all over Europe on 20, 17 and 15 meters SSB. This antenna is a keeper.

Paul, K4HKX

Thanks for this info Paul. Will check it out.

Now that 40 meter ten watt Ukraine SSB to me is not anecdotal, that is a great report actually.

Thanks for sharing!

ok I have a schematic for ed fongs jPole only are I am not sure about is the area I use rg174
If I understand I simply solder center core of bottom of 174 and the upper portion I short center core to shield and solder that shorted portion to the 300 ohm

heres a link to the schematic
http://i989.photobucket.com/albums/af20/WestTexasFishingAdventures/ScreenShot2014-01-23at30923PM_zpsba1a6a71.png

Heres a link to a drawing i made this is my understanding the photo is upside down sorry not sure how to flip it on photobucket....

Ron, I use a treated 4x4 wooden deck post 16/18 ft in length from Lowes, stood it up vertical with 18 to 24 inches in ground with half bag of instant concrete mix in it. I then put two/three of Lowes aluminum poles on side of post and secure same with electrical straps and wood screws. In top of post put a large eye bolt with a D ring and pulley with parachute cord down side for wire antenna for later use. I have four verticals for VHF/UHF and 10 meters install this way plus two HF wires. Works for me!

31072. 80m mobile on all bands?

Yahoo group: ham-antennas (2014)
Date: 2014-01-24 13:16:18 UTC
From: mikerodgerske5gbc@...
Topic: 31072 Message: 31072

Someone mentioned recently a friend using a 80m mobile antenna on 6-80 with a tuner.

When I asked K0BG about using a 11m antenna atop a screwdriver, he said there would be problems with coil windings arcing over SO would that also be a issue with above setup?

Are there guys/gals with actual first hand experience using the 80m with a tuner all band. I'm thinking if there is a arcing potential, a big can hustler might be better than say a ham stick ?

Thanks
Mike R

I have never heard of any arc over in such a situation. I used an 11 foot long mobile whip with
a coil about 2 feet up. It was a homemade classic "bug catcher. I used it on all bands with success, including 80m.

Many years of experience. Zero arc over. Now if you use 25 KW in a shoot out, then it might!

I have to agree with Paul, I played with a homebrew mag loop for 20m thru to 10m and found it to be a really good antenna, connected to my FT817nd I had decent reports with only 5w from most of Europe, Russia and North Africa from both horizontal and vertical pol. stations (did not seem to matter) and also a very good contact from Turkey by another loop user with his loop on a high balcony and mine indoors upstairs 5-7 given by me, 5-5 received in Turkey from here in NE UK, he was 30w. All contacts were on ssb.
Could be a very practical static/mobile antenna with a good remote tuning system (mine was basic manual variable cap with insulated shaft tube for tuning) I will say I had better results with a toroid ring feed rather than the second inner loop type of feed.
Plan to build another better one when we have moved qth also an 80m frame antenna.

Hi..

I did about the same thing as Wayne, N4HWH, but used 2x4 green treated lumber. The ground end was put into an opening in a buried building block and the top end was secured to the peak of the house.
It only held a tall 2m/70cm co-linear, so that was all the support needed. My lumber was about 18ft long, but bigger sizes are available. We pulled it down last year when the house roof was re-shingled. It had been up for ten years without any problems; looked like it could have gone another ten, or so.

For a small beam antenna, it would have been fine. For something larger, the size post suggested by Wayne would be better. I wouldn't have any qualms about using two pieces of 2x4, screwed together at right angles. Just depends on what is available at the local lumber yard; lots of stuff can be special ordered, if necessary.

Just remember, if its outside, make sure its green or brown treated lumber. Everything else will rot out in a couple of years.

Albert: Found them in the garden section on the outside. They are 10ft. each taper on one end so as to fit together. They are a little flimsy to mount up high due to wind, ice, storms. I use them to mount portable antennas for contesting when roving. I have 5 of these set-up at my home station at 20 to 25 ft high for vertical antennas. These poles are actually used as the top railing of a steel link fence. 73, Wayne

Not sure, but it has heritage to the ARRL reference antenna which was a stacked collinear. Same layout. I would start looking for a reference gain antenna variation. Good Luck.

For what it's worth, I have just made my 35 foot mast from 2 inch OD scaffold pole.

It has a swivel at the bottom and it is connected to my house wall with 2 K brackets.

I have used a 2 to 1 pulley system to raise it up and down.

As I have a have a 6 metre beam on it I also have a pole with a yoke so that when I lower it the mast it fits into the yoke and stops the beam hitting the ground.

I was going to have a 4 to 1 pulley but so many ropes tend to get tangled. I found that 2 to 1 was still very easy for one person to raise and lower.

You can pay quite a lot of money for this sort of thing but it cost me about 100 bucks in total.

It can be raised and lowered by one person on a windless day but probably best for 2 to do the job.

From: Roland Brade
Topic: 30989 Message: 31083

Firstly sorry I can't add this to my previous mail as I have trouble with yahoo groups, but to answer some questions. I bought my poles from a nice scaffold company man, although there are companies that sell them in 20 foot lengths over here. Using scaffold poles is really best as it has quite a thick wall.

The apex of my roof is about 26 foot. By pushing it up to about 35 foot it gives me a reasonable clearance and also allows me to add a cross arm to support my trap dipole.

I would have liked to push it up a bit higher to clear all the surrounding houses but I think I am OK where it is. My other bonus at this QTH is I am overlooking the sea and have a nice straight run towards Europe which I can see from here.

If you don't have a wall you can always guy it and use a jin-pole or gin-pole to raise it just as easily.

Happy building, a nice project for the summer months!!

...Exactly what I was thinking of using and what I mentioned in my message..... chain link top rail post.

I was looking into it and the top rail they sell at the stores in my area is usually 17 gauge and 1-3/8" OD.

Similar 10' "antenna" poles from channel master and the like are 1-1/4" and 18 gauge steel, so I think that the top rail will be a better choice for what I want to do.

Along with proper attachment to the eve/fascia of the house, and maybe a couple guys I believe it will be more than satisfactory for what I want to do.

Thanks,
Albert

Maybe vague wasn;t the right word.
I set the antenna up for phone as directed, ground mounted.
The only band even close was 10 meters.
What was confusing was what to do with 40 and 80 as changing the top section.
The recommended measurement was 22" but changing that from the minimum to the maximum had very little effect.
Alan's suggestion on removing a spoke (or two) kept me from having to "guess" at what to do next.

I'm the one referencing my friend, KD7LLF, that uses an antenna tuner with an 80M hamstick to work all bands. I was told by him that it works well on 20-40 as well as 80M. K0BG has a bunch of great information. I also have found some of his stuff, although it may have not worked for him, has worked for others and in some cases very well. I remember a TV commercial as of late "it was on the internet, so it has to be true!" and use that to temper what I read and study. There is that possibility that some writing on this forum have never done some things because they were told it couldn't work. Tesla was reported to have been told his ideas couldn't work by Edison, and that is why we all have neighborhood DC generators and no AC grid...OOPS.

Subject: [ham-antennas] 80m mobile on all bands?

Someone mentioned recently a friend using a 80m mobile antenna on 6-80 with a tuner.

When I asked K0BG about using a 11m antenna atop a screwdriver, he said there would be problems with coil windings arcing over SO would that also be a issue with above setup?

Are there guys/gals with actual first hand experience using the 80m with a tuner all band. I'm thinking if there is a arcing potential, a big can hustler might be better than say a ham stick ?

Thanks

I've used discones for many years, both commercial and homebrew, and had very good luck with them.

The trick is to remember that it is VERY broadband device, so noise can be an issue. I wouldn't suggest one if you are less than five miles or so from any high power transmitters.

The price for that broadband nature is gain. The best you will do is unity as compared to a dipole. In practice, it's usually less than that.

As an exercise (perhaps in futility!) I once built a discone with a low end cutoff just below 2m (like 142 MHz as I recall) and used sheet metal so the disk and cone were totally solid. Weighed like 30 pounds and I could see no practical difference in performance when compared to an MFJ unit with rods.

On, I didn't bother to calculate the wind load, but it was big!

go to the groups 'home page', and at the top it says 'search groups',
put your search term into this box,
click on 'search groups, and it'll search THIS group only for your search term.

It would have made more sense to say 'search GROUP' in the singular sense.

"... click on 'search groups, and it'll search THIS group only for your search term."

Unless it can't find a match in THIS group; and then it searches ALL groups for matching words in their group descriptions. And then you'll have to find a way back to this group again.

"It would have made more sense to say 'search GROUP' in the singular sense."

In the search box itself where you type the word(s) you want searched, it says "Search Conversations" which is more to the point.

Once you have searched once, an Advanced search option comes up, where you can narrow your search down.

Andy

Hi Gregg,

The good thing about a discone is the relative wide banded frequency coverage, both transmit and receive. The problem with a discone is the wide band frequency coverage....

Physically, you can get away with one of the cheap variety if it is mounted indoors, like an attic. They will have screw threads crimped into the ends of hollow stainless steel rods to make up the assembly. Very light duty, and easy to bend, even when moving it around inside your house. For outdoor use, you will need the expensive type; that is the rods making up the assembly will be solid stainless steel that has been threaded at the ends.

As others have said, its "flat and wide banded, with unity or less than unity gain". But, many times, that's all that is needed, especially at uhf and vhf.

They are a good all around antennas for local comms, 50Mhz and higher. If you are into experimenting with the cheap dvb-t dongles for SDR that cover 30mhz to 2ghz, it is the ideal antenna type. It will cover most of that range and perform adequately.

Discone antenna.

I have had several Discone antennas. I just built a new house and now getting around to antennas. I just received an MFJ Doscone and by far it is the best constructed one I have seen. Had solid aluminum rod construction. Well worth the money.

I've not seen anyone mention the real problem with discones. While they are in fact "broadband" as far as SWR is concerned, they do not radiate equally as well (at useful low vertical angles), on all frequencies.

Where they work fairly well (typically at 0 db gain), is on the more fundamental, or lowest frequencies they are cut for.

On higher and harmonic type frequencies and above, while they will take power with a reasonable SWR and will receive some signals and transmit at those higher frequencies, they do not radiate at very efficient vertical angles. Typically they will on those frequencies radiate well above the horizon at like 25 to 45 degrees and above with very poor performance on or near the horizon, where you usually want your RF to go.

I have a model made by Diamond. It is reasonably well made. I sometimes use it for local 2 meter repeaters and rag chews. Although it will also work the in-town 440 MHz repeaters, it doesn't work very well with those outside my immediate area. A simple dipole or ground plane cut for the frequency does noticeably better

Yep, 6M is what is set at for the coil and vertical. It runs well without it even attached, actually, unless you are specifically looking for 6M. Sustituting a hamstick or CB loaded whip also works, BTW. Not a solutuion for everything, but what single antenna is?

In the models, you're right, Ray. Discones appear to radiate fairly high.

In practice of using them since the early 1990s I haven't seen that to be a problem. I can hit 6m, 2m, 1.25m, and 70cm repeaters out to 30+ miles with 50w or less. I can work the 1200MHz machines to 20 miles with 10 watts.

My experience with discones is that getting it at least 20' in the air and having a solid ground on the mast is imperative.

I now have an MFJ unit (can't recall the model, but it's the one with 6m) on the end of 30' of EMT conduit. The antenna clamps to the mast, and the mast is firmly bonded to ground at the base.

While I have never actually measured the take off angle, in practice, it's a non issue.

Yes, even a ground plane would give better performance on a particular band, I have never seen one that will work from 50-2300 MHz.

I suppose I could get the ARRL handbook on antennas out and see about making a 6m loading coil and whip. That might be fun to try.

31109. Best Antenna For Small Backyard?

I live in a restricted neighborhood. Any antenna cannot be visible from the front of the home. I live in a 3 story so I can sneak some sort of antenna in the back yard. Other and maybe the main issue is back yard is 29 feet by 29 feet and to complicate things a swimming pool covers about 60% of yard.

So any suggestion on possible best antenna. I have read reviews on eHam and others. I have considered verticals like Cushcraft and others. I am not able to run ground radials (most of yard is concrete) and the pool is an issue. A beam would need a turning radius 14 feet max. MA5B Cushcraft or A3W would work. The mast or tower would have to be against back of house since power lines are at back of lot. One of my MUST is to have antenna and mast where if it falls cannot reach power lines. So another limit.
Any ideas would be appreciated?
For now I run mobile only. IC-7100, SGC 500 SmartPower Cube, HiQ 6-160.

Instead of a beam, you could build a cobweb antenna. It's a 5 band (20-10m) omnidirectional that works very well... Plus, they don't need a tuner and are easy to construct.

I would suggest the single wire style instead of the twin (speaker wire) because it's easier to time and has less weight/wind load.

Check out the discussion that was had about 6 months ago on the Zero-Five Vertical Antennas. I have a very limited lot were radials were not an option. I put up a**29 Foot Broadband 6 - 80 Meter Stealth HOA Multiband Vertical Antenna*. *It is on top of a 5 foot pole. It is working great for me. I work mostly on 80 meters and can make all of the contacts that I want.** I had a lot of questions for Tom and he patiently answered them all.

That will probably work just fine.

I built a chicken wire discone wire brazing rod supports once designed for just below 2m (around 135 as I recall) and later wanted 6m. I just added a 6m HamStick to the disk, and it worked well. SWR was a little high on the very low end of 6m, but I wasn't using it for anything other than FM work.

Quick and easy, but not nearly as much fun as your idea!

Look at the Hy-Gain series; AV-620 or AV-640. I have the AV-620 and like it.

From: roley_g3vir
Topic: 31114 Message: 31114

I bought a secondhand HF9V a couple of years ago and generally I am very pleased with the performance.
The only let down is 160 metres. It is rather short for this band at around 30 foot.
I wonder if anyone has done any mods to improve the performance on this band.
I thought I would look at modifications before I build a dedicated 160 metre inverted L.
Your comments are much appreciated.

George

When I started most of my antennas were in my attic, 2 meter 70 cm on mobile antennas on cookie sheets or traffic sign blanks, Copper J poles etc. My first venture outside I used Polly stealth cable from http://www.therfc.com/

My off set center feed dipole turned into a full dipole. Remember physical length doesn’t need to be in one line.

your advantage is three story heights. I used a 2 ft. piece of painted pipe from my roof vent at the start of the dipole.

Use some indignity the first antenna may not be the best or the last. You may go out to a tree or post and back to the house to make the length a diamond or a loop. Hide it in a tree or a flag pole in the front yard

Best of luck

Richard

George,

Take a look at the N6BT Bravo-5a. This is a relatively small half wavelength vertical, that does not require radials. Covers 20 through 10 meters. N6BNT also has models that will cover 40 and 80 meters.

Web site: http://www.n6bt.com/n6bt-Bravo-1.htm

Been there done that go the scars to prove ..... short version is build the inverted L.

Don't get me wrong , I love my HF9V and I have owned two over the last 30+ years and my current one is 20+ years old and still in service as my back up antenna. I no longer bother with the 160M add on kit (I use an Inv L instead)

But here is the science behind why it is really an exercise in futility to try and improve the B-nut on 160M. As it stands on 160 the B-Nut is basically a BASE LOADED vertical . To improve the RADIATION EFFICIENCY one needs to modify the antenna for TOP LOADING. This is usually done by removing the 160M base loading kit and then adding 2 to 4 wires to the top of the antenna, sloped back to the ground these will be on the order of 100' long. You could also add a loading coil at the top and then hook shorter top loading wires to the coil. This is NOT the same coil that you use at the bottom it will have many more turns. The biggest draw back to the top loading scheme is it largely destroys the resonance of the antenna on all the other bands and putting in a relay switching scheme to disconnect the top loading when not on 160M brings with it immense challenges of finding relays which can stand several KV of RF.

Dave
many thanks for taking the trouble to reply.
Yes, I have already thought about all the points you made and Thats why I went to plan an inverted L.
My antenna performs just great. Even on 160 it is not bad for local to mid distance.
I'd just like to work a bit of the DX that is around.
I get frustrated listening to a couple of friends working all the DX and I can't hear it!!
Still they bot have 100 foot verticals.
I shouldn't be greedy as I've done it all before but I decided to start again at my "new" QTH with a little garden or should I say back yard!
Very many thanks

Another thought is to invest in a SIGNIFICANT ground system under the HF9V. The effective radiation resistance of an antenna that short on 160M is on the order of less than 10 ohms so ground losses are a big deal. If the HF9V were my only option (due to lack of space and supports) I would (and have at past QTH's) put in a ground field of 50 or more ground mounted radials or go to 4 to 8 elevated radials this will help on Xmit ...hearing stuff on any vertical is tough regardless of the size and a low noise receiving systems (Loops and beverages) are worth the investment. I have worked Europe and Antarctica from the central USA using a HF9V and a KW on 160M. At the time I did have a 50+ ground radial system under it, but these were the exceptions rather than the rule. A full size Inverted L with a modest ground system will kick the HF9V's butt by a couple of S-Units every time. I am an avid DX'r with about 260+ countries on 160M and 99% of these were done with an Inverted L

I would think of running a wire around the eve of the roof, like where you would hang Christmas tree lights. I would use a OCF dipole so it would allow multiband use and not be visible. No towers and since you are 3 stories high it will be a chore to hang the antenna but the height will be to your advantage. I have used one like this when I lived in town in a restricted neighborhood. Good Luck

Yes Dave I agree with you. I already have quite a ground system with radials several hundred feet. They run on the border of other properties and were already in place as boundary markers! It works very well on the other bands but always lacking on 160 as you would expect. I can work North and South America but it is hard going. I'll just have to wait till the warmer weather comes to start building!! It gets very windy up here on the white cliffs overlooking France. Some of that bad weather from your side has arrived here now and the HF9V is bending like a goodun! It's quite amazing how well it works on 80 and the other bands. there is a photo of it on my QRZ page.

31124. Re: [ham-antennas] Re: "Short" vertical on 160 Metres

Yahoo group: ham-antennas (2014)
Date: 2014-01-28 18:11:03 UTC
From: Kenneth G. Gordon
Topic: 31114 Message: 31124

After reading the discussion on the Butternut HF9V on 160 meters, I am wondering what the collective wisdom might think about my vertical antenna.

In short, it is 55' tall, with a trap/loading coil at the 33' level. It was designed by a ham, now SK, who planned to market it as an 80/40 meter antenna, but who died before he got that far. What I have is the prototype, which I received in trade from the ham who helped the designer's widow disperse his radio gear.

I have installed only 4 ea 66 foot-long buried radials up to now.

The antenna has stood in place for at least the past 15 years, held up with clothes-line rope. The base insulator is made from PVC fittings.

I use it on all bands, including WARC bands, and up through 10 meters by means of my home-brew antenna coupler which matches it to 1:1 SWR.

The antenna is fed at the base with a buried length of RG-8. The RG-8 is about 40 feet long, although I have never actually measured it.

About 2 years ago, I wound a coil out of #12 solid wire on an old ribbed ceramic 4" diameter form (I think the form was made by National) with the idea of base-loading the antenna for use on 160 meters.

I found that I needed only 4 turns at most in order to resonate the antenna on 160. The bandwidth on 160 is very narrow, being on the order of only about 50 kHz at most before I need to change the tap on the loading coil. Moving up the band from 1800 Khz to 1900 Khz requires reducing the number of turns by at least one, for instance.

With this antenna and 100 watts, I have worked Europe. This was a big surprise to me.

Of course, the antenna is "noisy", but due to many restrictions, I can't do anything substantive about antennas at this point. I am pretty much stuck with it.

So, what might you folks think of this antenna's efficiency on 160 meters? Is there any way I could improve that, other than add more radials (which I have wanted to do for a number of years, but never got "a round tuit".)?

I have been gathering parts and have a design for a remote-controlled base loading system, but at the moment, in order to use the antenna on 160 meters, I must go outside and manually change the jumpers.

I've worked on many short verticals on low bands, so I'll throw in 2 cents.

Percentage wise, a 55' antenna is getting better in electrical length than a 26 foot Butternut for 160M. It is still not even 1/8 wavelength long however, so the efficiency on 160 is still going to be rather low. You just can't beat old man physics on this I am afraid.

For ground radials, you need more and longer radials, as you know. You want them at least as long as the antenna is tall. The 66' you mention should be just fine. (How are you using a feed line that is only 40' long?)

16 ground radials a bit longer than the antenna is tall is the beginning of where efficiency starts getting pretty good with ground radials, but that is with a 1/4 wave radiator. With a radiator less than 1/8 wave, more radials will certainly help, but since you are probably in the single digits efficiency wise due to the short antenna, I would not begin to venture how much it will help. It's simply a try it and see situation.

160M is tough for most hams to accomplish. Just work on the relays for changing the taps on the base coil and maybe add what radials you can as long as you can and call it a win!

I almost forgot to mention.... If you add more radials, you can expect two things; even narrower bandwidth and maybe a slightly higher SWR. But this is a GOOD thing, as it is an indication of improved efficiency. That may be counter intuitive, but it's the case with ground mounted Marconi verticals and more than I want to go into.

By connecting point A, the antenna coupler, to point B, the base of the antenna.:-)

The house is close to the base of the antenna: all the radials on the "house" side of the antenna have to bend around lots of obstructions. There are, essentially, no radials directly to the west of the antenna and for 20 feet on either side of the antenna. The base of the antenna is less than 20 feet from the house, and there is a concrete patio butting up against the west base of the antenna and for about 20 feet on either side of it.

Really neat, huh?

The drawing you're using doesn't look to be correct. The second gap in the twinlead shouldn't be there. See if this provides some clarity.

I was just advised that the antenna in question is a VHF/UHF jpole. I didn't catch that on Mr Fong's illustration.
So... never mind. I'll sit in the corner and remain quiet.

Maybe you could add a capacity hat somehow? (using metallic guys + insulators). There's a book from ARRL about 160m that might be useful, although it is technical, oriented to using NEC-4. It's also overpriced, IMO, so look in the library or used market.

From: Kd8nnu
Topic: 31109 Message: 31131

I have a cobweb single wire and it works real well at 40 fr.

I do use a tuner with it as it's not trimmed to perfection. Or in other words cut your wire a lot longer than the plans.

Subject: Re: [ham-antennas] Best Antenna For Small Backyard?

Instead of a beam, you could build a cobweb antenna. It's a 5 band (20-10m) omnidirectional that works very well... Plus, they don't need a tuner and are easy to construct.

I would suggest the single wire style instead of the twin (speaker wire) because it's easier to time and has less weight/wind load.

George,

I live on a "standard" sized lot in a HOA/CC&R restricted development. In fact, we are not supposed to have "ANY" ham radio antennas. Well, I've been here for over three years and have the following: 88 foot long doublet for 40-6 meters, Inverted L for 80 meters, Inverted L for 160 meters, a Hustler 5BTV ground mounted for diversity reception on my K3, and a roof-mounted home brew 5/4 wave vertical for 2 meters. No one has complained about any of these antennas. The doublet is my main operating antenna. It is made with very stealthy #26 "silky coat" wire from The Wireman in SC. The center support is a green windsurfing mast that I strapped to a second floor chimney. The top is 45 feet high. The doublet wires run from it through the trees in a mostly horizontal manner. The doublet is fed with about 110 feet of 450 ohm ladder line. At the shack end is a 4:1, 5KW balun and then 10 feet of RG-8X cable running to my station. I use an Elecraft K3, KPA500 amp, and KAT500 auto tuner. The doublet is a very, very good antenna when fed with ladder line, and I highly recommend it. It can be installed as an Inverted Vee, if necessary. You do need an antenna tuner to make it work, but that's a small price to pay for such a good performing, multi-band, stealthy antenna!

Hi George,

With vertical height, horizontal room, and ground plane all being issues you are likely limited to something on the order of an inverted L, or a induction loaded ground plane vertical like the 6-80 broadband ground plane made by Zero Five.
You may be able to tuck an Inverted L or bent dipole in the attic if you have access and ability to move around without falling through the sheetrock under the insulation. I do not like to crawl around in an attic because of the fiberglass and glass dust, but with care it is doable.
If you have enough space to set a vertical at least 12 feet from the house it can be installed about 7 feet above the ground so the radials are not a problem with use of the pool or back yard. If you happen to use a saltwater chlorination system in your pool, all the better as the slight salt in the water makes an excellent reflected ground to the radials.
Another option would be a flat beam like the ones sold in the states by Vibroplex for German firms. Either one of those can be mounted below the peak of the roof on ground mounted masts and pretty much be invisible from the front of the house, and are light enough to be easily installed.
I use a five band HD Spiderbeam and it is black. No one can see it once it is in the air. If you use Google Earth and fly over my home place you will see the shadow of my A3S on the garage roof, a glint of the two M3's on my house, and all that is visible of the Spiderbeam is a small square black shadow in the pasture west of the house.

31135. Off-center fed dipole with window line?

Yahoo group: ham-antennas (2014)
Date: 2014-01-30 00:01:48 UTC
From: <wa1rkt@...>
Topic: 31135 Message: 31135

I'm contemplating an off-center-fed inverted V for 160-80-40 fed with window line and a 4:1 balun to a tuner at the shack end, rather than putting the balun up at the antenna feedpoint and running coax to the shack. Reason is that in addition to its resonance points where it will provide a good match and low SWR, this antenna will also be used on frequencies widely divergent from its resonance points, using a wide-range autotuner at the shack end, and I'd prefer not to run 100 feet of coax at the resulting high SWR and high losses.

This works quite well with a center-fed inverted V and I'm wondering if there is a good reason not to do it with an OCF inverted V.

In this case it would because where this antenna is going, there isn't enough room to the property line to put a full-length 160-meter leg. There's plenty of room on the other side to put the long leg of an OCF inverted V.

I currently have a shortened center-fed inverted V, about 90 feet per leg, fed with window line but it's pretty marginal and won't tune on 160 at all. I figure I should be able to just lengthen one end to about 180 feet and leave everything else (other leg, feedline, center attach point, balun) as is.

Note that window line is balanced feedline and an OCF dipole or inverted V, by nature, isn't balanced, so I'm wondering if that will cause problems.

Hi Rick,

Depending on the design of the OCF dipole, that is the point of feed, the feed point and the length of the ladder line will produce a VERY wide range of impedance conditions to match. OCF antennas are quite capable of providing reasonable matches for a ATU. Other than that, it will work. I prefer to do some modelling and pick a ladder line length that is the best compromise on match conditions for the bands of interest. Not all bands will be good. Just an input.

In this case it would because where this antenna is going, there isn't enough room to the property line to put a full-length 160-meter leg. There's plenty of room on the other side to put the long leg of an OCF inverted V.

I currently have a shortened center-fed inverted V, about 90 feet per leg, fed with window line but it's pretty marginal and won't tune on 160 at all. I figure I should be able to just lengthen one end to about 180 feet and leave everything else (other leg, feedline, center attach point, balun) as is.

Note that window line is balanced feedline and an OCF dipole or inverted V, by nature, isn't balanced, so I'm wondering if that will cause problems.

I haven't figured out how to model ladder line, yet.

Are there length issues that are unique to OCF dipoles, or are the issues pretty much the same as for a center-fed dipole with ladder / window line?

A good remote tuner will let you match almost any piece of wire for antenna. Icom AH4 or SG Smart remote tuner will do you justice.
The Hex Beam would be a good choice. 12 feet is all you need. http://www.hexagonalbeam.com/
MFJ sell a Mag loop that is supposed to work well. Lots of plans on eham.net etc.
Ham Universe has lots to pick from: http://www.hamuniverse.com/antennas.html

Hope the links come thru.
Good Luck

>I live on a "standard" ; sized lot in a HOA/CC&R restricted development. In fact, we are not supposed to have "ANY" ham radio antennas. Well, I've been here for over three years and have the following: 88 foot long doublet for 40-6 meters, Inverted L for 80 meters, Inverted L for 160 meters, a Hustler 5BTV ground mounted for diversity reception on my K3, and a roof-mounted home brew 5/4 wave vertical for 2 meters. No one has complained about any of these antennas. The doublet is my main operating antenna. It is made with very stealthy #26 "silky coat" wire from The Wireman in SC. The center support is a green windsurfing mast that I strapped to a second floor chimney. The top is 45 feet high. The doublet wires run from it through the trees in a mostly horizontal manner. The doublet is fed with about 110 feet of 450 ohm ladder line. At the shack end is a 4:1, 5KW balun and then 10 feet of RG-8X cable running to my station. I use an Elecraft K3, KPA500 amp, and KAT500 auto tuner. The doublet is a very, very good antenna when fed with ladder line, and I highly recommend it. It can be installed as an Inverted Vee, if necessary. You do need an antenna tuner to make it work, but that's a small price to pay for such a good performing, multi-band, stealthy antenna!

Other and maybe the main issue is back yard is 29 feet by 29 feet and to complicate things a swimming pool covers about 60% of yard.
>>
>>
>>
>> So any suggestion on possible best antenna. I have read reviews on eHam and others. I have considered verticals like Cushcraft and others. I am not able to run ground radials (most of yard is concrete) and the pool is an issue. A beam would need a turning radius 14 feet max. MA5B Cushcraft or A3W would work. The mast or tower would have to be against back of house since power lines are at back of lot. One of my MUST is to have antenna and mast where if it falls cannot reach power lines. So another limit.

Yes, the issues are the same with the exception that the OCF antenna allows match impedances that are not the result of resonances. That is, on F2 you are not looking at a really high impedance. It helps letting the ATU do it's job better. What modelling program are you using?

The only problem with a hex or spider beam is you need a rotator. With a cobweb antenna, you don't. I do agree with the remote tuner (ah4 or sgc model) if you end up doing a wire antenna.

31147. Comparing GP-15 and V2000 antennas

Yahoo group: ham-antennas (2014)
Date: 2014-01-30 13:23:33 UTC
From: <hitekgearhead@...>
Topic: 31147 Message: 31147

I am looking at purchasing one of these verticals for 6m, 2m, & 70cm. I have begun looking online at reviews but haven't seen any direct comparisons. They actually look very similar in regards to specifications and design. The only difference I can see is that the diamond V2000 is two piece and the GP15 is one piece, and for 6m one (can't remember which right now) is a 1/2 wave and the other is a 5/8. Reviews are generally good for both of them.

Can anyone offer any direct comparison?

-Albert

I've got two Alpha Antennas due to arrive today (or maybe tomorrow), but haven't actually used any of them yet. However, I'll note that it's almost scary just how good of reviews they get on eham.net. I think the worst one I saw was one that got a score of "only" 4.9/5.0 possible.

You really just don't see that kind of thing on eham, especially when it comes to antennas.

The 2 legs will show different impedances to each leg of the ladderline ...
currents in the ladderline will not be equal and so the fields will not be
the same ... and so the line also will radiate somewhat (and pick up noise)

Good morning, Sigi.

Yeah, that's kind of what I was afraid of. I don't think I care if the feedline radiates, there is no objective to make the antenna directional in any way, or to avoid cross-polarization. As for noise, that may or may not be a problem, guess I'll have to just try it and see. What I don't want is RF in the shack causing problems with my computers. I'll be using a Balun Designs 4:1 current (choke) balun mounted under the roof eave outside the shack windows, with RG-8 coax from there to the tuner and window line from the balun to the antenna (approx 60 feet). Transmit power output will be approx. 600-700 watts.

I suppose I could mount the balun at the feedpoint at the top of the tower and run coax from there to the shack, but I'll be using this antenna on MARS and CAP frequencies that are well outside the ham bands, and on those frequencies the SWR will be very high. I won't be able to do that until sometime in the spring, and anyway I'm trying to figure out whether I'll be better off with low-loss open wire line (and live with the imbalance) or high losses in a 60-foot length of coax.

SigJoe..YOU'RE funny! LOL! (A dummy load...heh...Hey! For fun, we used to talk on dummy loads [And light bulbs!] all the time, locally!)

****

John,

Depending on the amount of room you have on your property...Best antenna? Crap shoot....If you have the room, a flat-top dipole of some sort...I prefer the Windom, off center fed.....to cover 160, you will need to be able to string a 240 +- foot wire and optimally at 32 feet in height, although 22 feet works fine.

If room is an issue and you have no CC&R's, something like a Hygain Hi-Tower (AV-18HV) with the 160 meter coil works quite well. (My favorite all band vertical..but *is* very expensive,as it is a 20' tower with radiating elements attached for the different bands)
They also have a non tower based vertical as well...,
Go here to view all the HyGain product line: http://www.hy-gain.com/productsearch.php

Another popular series of all band verticals, is the Gap antenna line...
Go here to view: http://www.gapantenna.com/

Check MFJ Enterprises for various antennas as well.

There are *many* antenna possibilities, and every one will have its supporters, as well as its nay-sayers.
Don't forget, if you seriously look at verticals, don't forget, no matter what the ads say, some sort of ground plane (Specific lengths of wire, radiating out from the base of the antenna) *will* be needed.

Have fun looking and searching!

Yup we did the dummy's local and light bulbs too.

Couldn't resist the dummy load. Main reason saying is on those bands, 160, 80, 40, a good SWR all over is a good sign also that the antenna is very lossy.

Just something to remember.

From: Scott Myers
Topic: 31151 Message: 31156

I know Joe was being funny with the Cantenna, but I think the point he is making is that low SWR does NOT mean that it is a good antenna. So the question is, why the concern with the lowest possible SWR?

When you get to the low bands, you are not going to get antennas that are going to cover the entire band without relays, matching coils, adjustable length elements, etc. It's a world of trade-offs on the low bands.

73,

Scott AC8DE

I have a topbandloop fed with ladderline and homebrewed balun ... tuner is set to bypass on most bands ...

I had to trim the ladderline AND the loop till I found that "sweet spot" I was searching for (low swr on nearly all bands) but finally it worked

... another option (if you only look for those 3 bands) woukld be a fan dipole

what radiates does also receive!!

So it will pick up your computer noise (and all other noise that is mostly
vertical polarized)

there is no objective to make the antenna directional
> in any way, or to avoid cross-polarization. As for noise, that may or may
> not be a problem, guess I'll have to just try it and see.

What I don't
> want is RF in the shack causing problems with my computers. I'll be using

> output will be approx. 600-700 watts.

Quick test ... disconnect only the shield of the coax ... does the noise
increase?!? (guessing yes)

>
> I suppose I could mount the balun at the feedpoint at the top of the tower

> sometime in the spring, and anyway I'm trying to figure out whether I'll
> be better off with low-loss open wire line (and live with the imbalance)
> or high losses in a 60-foot length of coax.

Other way around would be best ... ladderline ALL down to shack

Avoid that lossy coax (especially when using with high swr)

2 times "something" works on ALL bands when fed with ladderline

(been there ... done that "a thousand times" on fieldday)

A quick calculation "over the thumb" and you will know what impedances you
have to deal with depending on what lengths of ladderline and what length of
dipole/doublet is used (and then either select 1:1 or 1:4 balun)

Dg9bfc
```

Sigi

Ps balun could be made switchable 1:1/1:4

I am not much for buying some antenna that covers all band with a low SWR. Most that do have a lot of loss unless you use Joe's idea with duel use. For wide band coverage you need a cage dipole and they are simple to make. They are in any antenna book. If you make it a fan dipole you can cover all three with one antenna. I have a 160 dipole with a 80 fan element. It is fed with 450 ohm line into my shack then a 4:1 balun sitting on top of my tuner. I could not get 1:1 SWR on all bands with MFJ's built in balun so I made my own. I can work 160 thru 10M with one antenna. It is great off the ends on 10M because of the lobes of operating a 160 antenna on 10 but a little hard to rotate. To get low SWR I made my balun switchable as a 4:1 or 1:1.

http://s1102.photobucket.com/user/KD0ZZ/media/4to11to12.jpg.html

I have had successes with wide band cage verticals having a low SWR over a wide range and fan antennas, but have never put them together.

Gentlemen,
who is a good way to measure the efficency of an antenna?

Hal AA2ID

Couldn't resist the dummy load. Main reason saying is on those bands, 160, 80, 40, a good SWR all over is a good sign also that the antenna is very lossy.

Just something to remember.

****

John,

Depending on the amount of room you have on your property...Best antenna? Crap shoot....If you have the room, a flat-top dipole of some sort...I prefer the Windom, off center fed.....to cover 160, you will need to be able to string a 240 +- foot wire and optimally at 32 feet in height, although 22 feet works fine.

If room is an issue and you have no CC&R's, something like a Hygain Hi-Tower (AV-18HV) with the 160 meter coil works quite well. (My favorite all band vertical..but *is* very expensive,as it is a 20' tower with radiating elements attached for the different bands) They also have a non tower based vertical as well...,

Go here to view all the HyGain product line: http://www.hy-gain.com/productsearch.php

Another popular series of all band verticals, is the Gap antenna line...

Go here to view: http://www.gapantenna.com/

Check MFJ Enterprises for various antennas as well.

There are *many* antenna possibilities, and every one will have its supporters, as well as its nay-sayers.

Don't forget, if you seriously look at verticals, don't forget, no matter what the ads say, some sort of ground plane (Specific lengths of wire, radiating out from the base of the antenna) *will* be needed.

Have fun looking and searching!

SigActually, there is, but it’s not all that wonderful.

A company, B&W, Barker and Williamson, of Bristol Pa., offers a folded dipole that is very broad banded. But, and this is a BIG BUT, it does so by inserting a resistor in the radiating element. It does soften... or flatten the SWR curve, but it does so by wasting a good percentage of your signal as heat. Sort' a like a radiating dummy load... that can like device that the link in the previous message sends you to. There have been other discussions on it and I’m only relating what I’ve read in this forum.

Antennas of this type do have a place however, IIRC, the military finds them useful as they will tune up easily, almost anywhere, the kind of behavior they would need in the field. We, on the other hand are usually looking for the best signals in and out. That antenna doesn’t deliver that.

>> shield of the coax ... does the noise increase?!?

A bit, maybe 1/2 of an "S" unit at the most. It's tolerable.

Note that the so-called Carolina Windom OCF dipole has a vertically-polarized element, by design.

>> Other way around would be best ... ladderline ALL down to shack

That's puts too much RF in the shack. I've tried it. For a center-fed antenna, not too bad, but as you pointed out, for an OCF antenna the feedline radiates... including the portion of feedline that would be inside the shack in that configuration.

>> A quick calculation "over the thumb" and you will know
>> what impedances you have to deal with depending on what
>> lengths of ladderline and what length of dipole/doublet
>> is used (and then either select 1:1 or 1:4 balun)

I'll be using this on military and amateur frequencies from just below 160 meters to a bit above 20 meters, including some frequencies that are fairly distant from any amateur band. So I really can't pick a frequency or even a harmonically-related list of frequencies and figure out feedline lengths and balun ratios, because what works on one won't work on another.

I have another, full-size 160 meter center-fed inverted V fed with window line, which I can use on frequencies where the OCF inverted V won't work, and vice versa. There are places where the full-size center fed V won't work, either.

>> Ps balun could be made switchable 1:1/1:4

I have one of those, unfortunately it's only good for up to 100 watts, plus it's a voltage balun. I use it with my FT-817, my rescued-from-CB-hell HF amp, and a field antenna for portable field work.

A switchable legal-limit-at-any-SWR current balun might not be so easy, unless I just install two baluns and some big relays to switch from one to the other.

If anyone has a design for a remote-switchable legal-limit-at-any-SWR current balun I'd really like to see it. :-)

Geoff

Essentially as you say more useful to think of this as a top loaded vertical or Inverted L, The vertical "feed-line" will radiate..Depending on the lengths of the two sections in wavelengths (or fractions there of) there will be both horizontal and vertical radiation.

Topic: 31114 Message: 31166

Ken,

Assuming you have average ground conductivity, your efficiency is very low on 160 with only 4 radials so you need to add more radials. If you get up to 16 radials, you will be about 3 db down from a perfect ground system (120 1/4 wave radials). At about 32 you will be about 1.5 db down, and at 64 you will be 1 db down from a perfect ground system. A good ground system is EXTREMELY important to vertical's performance and becomes more so as the physical length is reduced. A 55 foot vertical can perform very well if the ground system is good.

Some say an elevated vertical with 10-12 elevated radials rivals a perfect ground system. I use a base loaded 60 foot vertical with 8 elevated 1/4 wave radials and it works reasonably well on 160.

Hi John,

You've already heard the best and worst of the responses to your question!

There is no "best antenna", especially at those frequencies. On a high band you might be able to cover most of the band with one "antenna setting", but on the lowest band you will only cover 5 or 10khz before you have to make some type of adjustment. For efficiency, the best adjustments would be at the antenna; for convenience, an antenna tuner next to the radio would make the equipment happy.

Much depends on how much space, native physical supports, funding, and the work your willing to expend. One extreme would be the array at Radio Arcala....

http://www.pa2old.nl/page.php?id=271

which suffered a lot of damage in a recent storm.

The other extreme would be an antenna tuner used with a long piece of wire strung through the tree branches.

Personally, I like the inverted "L". You can make your own multiband "L", or make only part of it. Examples of both types.....

http://www.hamuniverse.com/k8kas160104btvmultibandantenna.html

The Hustler xBTV series has been around a long time, built like a tank, and available used at very moderate prices. New prices are good compared to other antennas.

If you want to make your own, check out the following links.....

https://sites.google.com/site/trapantenna/home
and
https://sites.google.com/site/trapantenna/about-the-antenna

If two links above don't work, search using Google with the name and callsign, Bob Rice VE3HKY .

You might want to read this article. Its about 45 years old, but will give you some insight....

"Which Aerial by G3RNL", and it can be found at

While the rear bumper mount location worked well. I kept having to be very careful backing up as I could not see the antenna and how close I was to obstructions.

So, I moved the antenna forward and up higher. Photos in my file.

From: roley_g3vir
Topic: 31114 Message: 31174

Today the weather was dry but very cold so I quickly hooked up a wire inverted L.
The vertical is only 20 foot and the rest goes down the end of my garden. However with this very basic L it is already performing on a par with the HF9V.
Can't wait for the warmer weather to come to get the vertical up to 40 or 50 foot. That should make a great improvement. I also connected into the existing radial system for the HF9V.

>
> Yes Dave I agree with you. I already have quite a ground system with radials several hundred feet. They run on the border of other properties and were already in place as boundary markers! It works very well on the other bands but always lacking on 160 as you would expect. I can work North and South America but it is hard going. I'll just have to wait till the warmer weather comes to start building!! It gets very windy up here on the white cliffs overlooking France. Some of that bad weather from your side has arrived here now and the HF9V is bending like a goodun! It's quite amazing how well it works on 80 and the other bands. there is a photo of it on my QRZ page.

From: Rick Poole WA1RKT
Topic: 31176 Message: 31176

In his paper "The Balun and the UnUn" (www.philipstorr.id.au/radio/technical/Balun%20and%20UnUn.pdf□), Phil Storr VK5SRP makes some claims:

```
1. A voltage balun uses transformer action to convert between unbalanced and balanced; the
transformer turns ratio controls the impedance transformation ratio (1:1, 4:1, 9:1, etc.).

2. A current balun allows working currents to pass but chokes common mode currents -
nothing more. There is no transformer action.

3. Because it is a current controlling device and not a transformer, there can be no such
thing as a 4:1 current Balun.

Uhh... OK. Yet I see 4:1 (and other XX:1) current baluns advertised all over the place.

So what's the deal?

Rick WA1RKT
```

31177. File - rules2.txt

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

It seems to me that this paper (which I read) and the underlying material at http://vk5ajl.com/projects/baluns.php (I also read this) support the assertion that "every man is entitled to his opinions, even if wrong." Mostly what vk5ajl seems to be doing is to re-define "current balun" and even "balun" in novel and I imagine controversial ways and then assert the impossibility of a current balun with an impedance transformation ratio of other than 1:1.

I can prove the impossibility of a three-wheeled automobile by defining an automobile as having four wheels. (Some US state motor vehicle bureaus do this.)

Neither in the paper nor on vk5ajl's page is there any pesky mathematics. The problem is that all their claims are amenable to both theoretical and modeling proofs as well as direct engineering experiment and measurement. None of these measurements would be about SWR, rather voltages, currents and impedances (the basic quantities) would be measured. This can get expensive. The amateur literature on baluns is fairly devoid of actual measurements of a fundamental nature. Instead, we substitute words and sophistry, appeals to common sense and cite DX contacts as proof of theories. The ARRL with its /*apparent*/ policy of not publishing material with math beyond high school bears some of the blame for this. As someone else on one of these lists remarks in his .sig, the fact that an 8 year old can get an Extra class license should tell us something.

So I say to take this one with a grain of salt. It should require an M.S. in E.E. to speak publicly about balun theory. I lack one of those.

"No theory? And no measurements? Then you have no science."

31180. Need 4:1 unun (do I need a current-type?)

Yahoo group: ham-antennas (2014)
Date: 2014-02-02 01:34:01 UTC
From: Rick Poole WA1RKT
Topic: 31180 Message: 31180

I have a 160-meter inverted V that I use throughout the HF spectrum, on the ham bands and on frequencies that are outside, sometimes fairly far outside, of the ham bands (CAP, MARS, and perhaps eventually, SHARES).

The feedline is balanced window line and yes, I know about tweaking the feedline length so it's an odd multiple of 1/8 wavelength at the lowest frequency. That rule assumes that one is going to be using harmonically-related frequencies, e.g. in the ham bands. That's not the case here and so there is no single feedline length that won't leave a significant number of the target frequencies "out in the cold" so to speak.

The feedline goes to a 1:1 Balun Designs current balun mounted outside my shack window, and thence over a short length of RG-8 to an LDG autotuner in the shack. It all works reasonably well except, as I said, there are several of the frequencies of interest that just won't tune with the LDG.

The LDG tuner has two antenna connections and so I thought I would try feeding the feedline to a coax switch, one side of which goes to the tuner's Antenna A connector and the other side to Antenna B thru a 4:1 unun. Then if the tuner won't tune with one, I can switch to the other and try that.

My question is, do I need a current unun? Or will a voltage unun do just as well? Seems like the objective of a current balun, to force equal currents in each leg of the ladder line, is taken care of with the 1:1 Balun Designs current balun, so I shouldn't need to do it again at the antenna tuner end, right?

Next question is, what really is the difference between a balun and an unun? Seems kind of obvious but I've seen many instances where a balun is indicated for feeding a vertical which is unbalanced by nature, and I've also seen cases where someone just wires an SO-239 connector to the balanced antenna studs and calls it an unun. Can't be that simple.

Anybody got a design for a legal-limit capable 4:1 unun?

Thanks...

Rick WA1RKT

Rick,

My antenna system is "kinda" similar. I have an 88 foot long doublet (#26 "stealth" wire) that runs horizontally 45 feet high. It is connected at the center to about 110 feet of 450 ohm ladder line. Just outside the shack the ladder line connects to a Balun Designs 4:1 5KW balun (model 4114T), and from there about 10 feet of RG-8 into the back of an Elecraft KAT500 auto tuner. That balun was recommended by Bob at Balun Designs after I explained to him what my antenna and transmission line were made of. The tuner finds a 1.2:1 or better match for me on all bands, 40 through 6 meters. It probably would work on 80, but I have a fairly tall Inverted L for 80 so I have no need to use the doublet on that band. Anyway, you may want to give that special 4:1 balun a try and see if it performs any better than the 1:1.

Rick, a balun . Balanced output unbalance input. Unun unbalanced input unbalanced output although an impedance change gas occurred. If you ard using twin feed itscs balun your needing if its and rf choke then a 1:1 unun would stop common mode rf.

You use a 1/1 balun in verticals if the feed point us raised bring the feed point to 48 ohms approx. once it becomes raised the 1/4 radials are part of a balanced tuned circuit so a balun is used. If radials are random length and Radom quantities tg db an unun would be used to stop common mode rf.

>> although an impedance change gas occurred.

Yup, I know all of that.

What I'm looking for is the difference in configuration and connection between a 4:1 balun and a 4:1 unun, since the very few diagrams I have seen seem to indicate that the unun is little if anything more than a balun to which someone connected a coax on the balanced end.

Also, the question remains about whether, in the configuration I described, I need a current-type 4:1 unun at the tuner end, or will a voltage-type do?

I have a GP-15 and it works just fine for 6m, 2m, 70cm FM repeater work. The only thing I wish was that it could tune to the lower end of 6m (with low SWR) for SSB. I suppose one could add a slightly longer stinger to the 6m element to do that, but then you wouldn't be able to work the upper end ofb the band.

I have no experience with the Diamond antenna so can't comment on it.

Rick

I've attached a drawing if a 4/1 balun. Will look for a 4:1unjn. The difference is not adding a piece of coax. An 4:1 unun uses Trifler windings similar to a 9:1 unun.

I find current baluns are good for resonant antennas example OCF dipoles. However have used 4:1 voltage baluns regular in your set up. Removing your 1:2 balun putting the 4:1 at the atu and twin feed straight to the atu will give you a doublet antenna.

Good morning, Billy.

Apparently the ham-antennas reflector doesn't allow file attachments. You can send the file directly to me at wa1rkt@... if you wish.

I've seen a drawing for a 1:1 balun vs unun that seems to indicate that the radio-side coax connector connections are reversed for an unun vs a balun. Not sure why that would be, nor any idea whether this person knows what he's talking about. Anyway it's a 1:1 where I need a 4:1.

I haven't gotten a direct answer to my question of whether the unun needs to be current-type, or a voltage-type will do. A current-type balun (as contrasted with unun) forces equal currents on each side of a balanced antenna or feedline. This antenna uses one of those (a 1:1) outside the shack window to translate between balanced line and coax. My thinking is that I shouldn't need to do that again at the tuner end with the 4:1, and a simple 4:1 impedance transformer (voltage type) should be all I need there. Can someone tell me whether I'm right or wrong on this?

>> Removing your 1:2 balun putting the 4:1 at the atu and twin
>> feed straight to the atu will give you a doublet antenna.

I don't have a 1:2, it's a 1:1. But in any case, running the ladder line into the shack and connecting it to the back of the tuner will result in too much RF in the shack (I know, if things are set up correctly it should not do that, but it does). It's fine at 100 or 200 watts but I'm running 700 watts on one station and 1000-1200 watts on two others and I run several computers here that I don't want to take a chance on rebooting or corrupting them when I transmit. That hasn't happened here yet and I'd prefer to keep it that way.

Hi rick,

My thoughts are the ladder line is balanced and cancel each other out so the 4:1 is purely for impedance matching. The voltage balun would do. Ill email you this'd files over.

31200. 2m 70cm ferrite choke balun

Yahoo group: ham-antennas (2014)
Date: 2014-02-02 18:55:06 UTC
From: Jimmie K9JFK
Topic: 31200 Message: 31200

Hi,

I'm about to make a couple of dual band roll-up type j-poles for 2m and the 70cm band. I sincerely doubt the ability of coax coil loops to form a choke that will operated on both of the bands. I've looked at many web pages trying to find reliable information on using ferrite beads at vhf and uhf, but cannot find any other than anecdotal.... "no problems, seems to work fine"... etc. Even if it is possible, I don't want the size or the losses associated with a coax choke balun, likely made from rg174 or rg58.

Does anyone have some, or know of a location, of some hard data? I know this could be "shotgunned" by using a couple of large snap on ferrite cores, but that is not the style I want on these antennas.

My current test equipment is an MFJ259B and an old Allied Radio SWR meter. The MFJ doesn't go up to 70cm, and the Allied SWR meter is only good to 400mhz. In my experience at lower frequencies, rf on the outer part of the shield causes "hand effects". That is, the meter readings change as parts of your body and hands move along the transmission line. So, that is what I currently have to work with; my body and two pieces of equipment.

Someone will suggest making a five turn coil of coax about 4 inches in diameter. That is an ineffective choke on 2m; the coil actually needs to be about 4 turns/1.5 inches in diameter and something else on 70cm. I doubt if that choke would be effective on the whole 2m band or at 440mhz.

These j-poles will be used with HT's. I've set the design's power limit at 50w, just in case its used with a mobile unit.

I've spent some time looking at ferrite materials and found mention of types 31, 43, and 61. However, the specs on some "type numbers" don't match between manufacturers. One company's UHF material number doesn't have the same specs as another manufacturer. So, I assume that manufacture's name must be used with the "material type number". True or Not???

Any opinions and informational web pages welcomed!

73, Jimmie, K9JFK

Hello Jimmie,

While I have not tried this on a simple roll up J, I do believe that you could make a pair of decoupling sleeves. It is standard practice to put a shorted sleeve on the coax to decouple any RF on the shield of the coax. I would suggest that you could fabricate a shorted sleeve for 70 cm just after the attachment to the J go down a 1/4 wave on 2 m and do the same for that band. I have made portable decoupling sleeves in the following manner. Put a connector with a barrel as close to the feed point as practical. On the coax connector going to the radio put on a 70 cm 1/4 wave of shield from a stripped coax of the next size. Put a piece of heat shrink over it to hold it in place. Measure down 1/4 wave on 2m and put another connector/barrel/connector a put a 1/4 wave shield for 2m and repeat the process. I soldered the braid to the connector on the feed side and that way it is secured with the heat shrink. The good part of this is that you can disassemble the feed line easily. That ought of to the trick. Have I seen any hard articles on doing it, there have been a few construction ones but nothing that come to mind. Good luck.

Hi Mel,

Thanks for the information, it is something I never considered!

Checked over a couple of web pages and found some discussion of the subject. While I'm still leaning towards the simplicity of ferrite for a choke balun, I think it would interesting to compare working models against each other.

Spring doesn't seem to be hiding around any corners, yet, so I've got some time to build a couple of antennas for comparison. Will need warmer weather to run some test in the backyard, though. We are in the middle of a heat wave here... the temperature is expected to get up over 0 degrees F with today's sunshine (Wisconsin). I would've made a really lousy Canadian... they have it much worse!

On the ferrite side, I would tend to look at the core types that they use for VHF/UHF TV baluns. I don't know the type, but am sure you can find it at Amidon or Fairite. Bigger core of course.

Many years ago, 40 to 50, sorry showing my age. J Beam in England came up with an "inside out" balun for it's VHF & UHF A/E range. They took 100 watts or so and used what looked to be about the same size core as a TV balun.

I don't recall actually having seen one and could never quite understand the workings of them. Should be info on the net or maybe an old time G8*** will have had actual experience.

Cheers

31205. Diamond discone Antenna swr problem

Yahoo group: ham-antennas (2014)
Date: 2014-02-03 23:17:43 UTC
From: <chuckl689@...>
Topic: 31205 Message: 31205

Hi all,
I own a diamond discone antenna that I installed in the attic. It is being feed by 60ft long piece of coax (914) The swr is great around 145.00 however when I go to 147+ the swr rises to about 2.1 to 1. I have tried different lengths of the stinger element but no change. I have tried different coax....got better swr and worse performance.
I am thinking that I have to really cut down the stinger a bunch (maybe 2inches or so) before I get what I want.
(The repeaters that I use all are in the 147+ range.)
You comments could help me out,
Thanks
Chuck

Are you talking about the 'stinger' sticking up straight out of the top? If so, that is most likely for 6m, not 2m and adjusting it won't give you the results you're seeking.

From: Andy
Topic: 31205 Message: 31207

I don't own a discone ... however it is my understanding that the stinger element is there ONLY to make the antenna work on 50 MHz (or whatever its lowest band is), where the disk/cone part is too small to be effective. It should have ~no effect on 2 meters and above and can probably even be removed if you don't need 6 meters. You might try doing that in case it does make a difference.

Can you shorten any of the angled elements? I think those are the ones that have a bigger effect near the lower end of the normal discone passband.

I am slightly surprised the SWR changes that rapidly. A discone is supposed to be extremely wideband; the SWR does wiggle up and down somewhat, but I'd think the wiggles wouldn't have been that tight.

I wonder if there is anything near the antenna in your attic that is detuning it?

Andy

As the reply after mine stated, a discone is very broadbanded an he (as am I) is surprised with the sharp swr changes you're experiencing. AFAIK there aren't any adjustments you can make, however, a look in the manual might indicate differently.

Hi, Chuck...

First of all, DO NOT trim any of the elements. Ever!!

You can remove the stinger if you don't use 6m, however.

You have one of two problems (maybe both!) with your discone:

(1) Something in the attic or surrounding roof is detuning the antenna. To test this, you can either move it around in the attic or bring it outside. If you can get it 10' off the ground, it will work well enough for the tests. Once you have done this, see what happens to your SWR. If it goes flat (from about 130 MHz to around 1200 MHz), you have something up there coupling to the antenna.

(2) Grounding issues. Make sure that the coax shield is well grounded (RF ground, NOT simple electrical ground) OR (yes) totally isolated from ground until it connects to the rig. Discones are sensitive to ground loops and they will display behavior like what you describe.

Personally, I suspect #1 above. In your type of installations, ground loops are rare.

Take Care & 73

I tend to agree, the antenna is designed to preform out of the box.

I too have antennas in the attic and use them on 2 meters.

How are you testing your SWR, meter and radio? Or an antenna tester analyzer?

How are you grounding the radio and coax?

Wet roof with snow covered within inches of the antenna?

Food for thought

Richard

Subject: Re: [ham-antennas] Diamond discone Antenna swr problem

Hi, Chuck...

First of all, DO NOT trim any of the elements. Ever!!

You can remove the stinger if you don't use 6m, however.

You have one of two problems (maybe both!) with your discone:

(1) Something in the attic or surrounding roof is detuning the antenna. To test this, you can either move it around in the attic or bring it outside. If you can get it 10' off the ground, it will work well enough for the tests. Once you have done this, see what happens to your SWR. If it goes flat (from about 130 MHz to around 1200 MHz), you have something up there coupling to the antenna.

(2) Grounding issues. Make sure that the coax shield is well grounded (RF ground, NOT simple electrical ground) OR (yes) totally isolated from ground until it connects to the rig. Discones are sensitive to ground loops and they will display behavior like what you describe.

Personally, I suspect #1 above. In your type of installations, ground loops are rare.

Hi all,

I own a diamond discone antenna that I installed in the attic. It is being feed by 60ft long piece of coax (914) The swr is great around 145.00 however when I go to 147+ the swr rises to about 2.1 to 1. I have tried different lengths of the stinger element but no change. I have tried different coax....got better swr and worse performance.

I am thinking that I have to really cut down the stinger a bunch (maybe 2inches or so) before I get what I want.

(The repeaters that I use all are in the 147+ range.)

You comments could help me out,

Thanks

Chuck

Hi,

1. I moved the antenna and that helped a little--- down to 1.7 at 177+ (I am working on it in between typing)
2. Measuring SWR with a Daiwa cn801 meter---- range 140 to 525mHz
3. Grounding could be an issue I don't have a good RF ground
4. and I note that one element of the cone is about 3 inches short due to a failure (got bent fell off)
5. Bringing the antenna outside is not an option.....I live in an HOA environment and there is a provision against out door antennas.
6. the tip of the 6 meter element is about 3 inches from the roof which is ply wood and standard shingle with nails.

Chuck...

OK, that kind of confirms that you have the antenna coupling to
something. At 2m and up, that could be anything from electrical wiring
to flashing to rain gutters.

Also, the broken element is problematic. Take some wire (#14 is fine)
and make a few wraps around the end of that element and then run it out
to about the same length as the good elements. That will do the trick there.

Are you using the antenna on 6m? If not, take the stinger off to get
things away from the roof.

From: Jim
Topic: 31205 Message: 31215

Hi Chuck,

First of all, the stinger is an electrical "after thought" and effects only 6m operation. If you want, just take it off! Second, there is probably nothing in you attic that is "detuning" your discone. In my experience, discones don't have any "tuning". If in doubt, unscrew a spoke or hat rod!

I currently have a discone hanging in my basement, about 4ft off the ground. Doesn't work the best there, of course, but well enough to play with. The short spokes screw into the top and will be horizontal; the longer spokes screw in to the hub and will form about a 60 or 65 degree angle when done. Screw all the spokes in just hand tight and then tighten the jam nuts slightly... that's it. You've done all that you can do! There is no other way to tune the discone! Other than connecting the support pipe to the "hub" and passing your coax through it, your job is over! Nothing else you can do to effect "low swr" operation of the antenna.... except at 6meters. There, you can raise and lower the "stinger" for a better swr for transmit.

Aside from what the ads tell us, the discone is a wideband antenna that is primarily meant for receiving operations. Its a real boon to those of us into SDR radio based on the dvb-t dongles; allows us to receive from 30mhz to 1.4ghz. The discone does not have a "perfectly flat" swr across a broad spectrum. There's lots of peaks and valleys!

I've used the discone for transmitting at 2m and 70cm; my experiences match yours at 2m. The swr is neither flat nor constant from one end of the band to the other. I presume it is the same way on 70cm, but my MFJ259b will not go that high. I've used both mobile units and HTs on the discone; at no time has any of the equipment overheated or given me a problem. If the swr is below 3:1, I don't give it a second thought!

So, relax. Hacking on your discone will not effectively tune your antenna for amateur band operations. It is primarily a receive only antenna that is passable for amateur operation. The antenna will never be "flat". Only a dummy load is "flat", and then, only over a specified frequency range; there is no "magic bullet" antenna.

If you want something better for amateur operations on 2m and 70cm, may I suggest a j-pole? Or a standard ground plane? You can make either one of those without much of a problem or expense.

If you want to build I have had good luck with this antenna.
<http://www.n1gy.com/ocfd-dual-band-antenna-version-2.html>
or
<http://www.n1gy.com/ocfd-dual-band-antenna-version-1.html>

I'm thinking about building one of these myself.
<http://www.dxzone.com/dx20279/vhf-uhf-dualband-vertical-antenna.html>

If your wanting to purchase I have no idea as I've never purchased base
antennas so have no experience with that.

Hi all,

So the following actions resulted in the following (it is a DN-130 Diamond Discone mounted in attic)

1. removed the 6 meter whip/stinger.....no change
2. increased the distance between objects and quick fix the one short element in the cone
Some more change.....now down to 1.5 to one at 147+ (where the problem is) Also as expected the maximum power out is now about 65 watts out of an icom 2200H

I don't know if I can get any more short of mounting it outside which is not going to happen.

Thanks all for great suggestions...

Chuck

I think that's about as good as it's gonna get, Chuck.

Every discone I have used over the last 20+ years I have had 1.7:1 or
less from 130-ish up to 1200-ish. That includes the exact antenna you have.

But, as someone said, there are no magic antennas.

Glad to have been of help!

What do you want to spend? where do you want to mount it? How much power?

Do you need to hid it?

I have a copper J pole in the attic, using a Motorola Maxtrac at 45 Watts

I cover 20 repeaters.

I have a mobile antenna mounted on the cap of the chimney and hit 30 stations.

an average $ 50.00 base station Comet to a 8 Ft $200.00 Fiberglass

Using RG 231 cable

What do you need to cover

If you need omni, you are looking at either a slim jim (which has a nice low takeoff angle and about 5 db gain) - or a colinear, which could have significantly more gain with a more squished pattern...Slim jim can be made of ladder line or 300 ohm TV line... the colinear, coax.

If you are thinking directional, a cubical quad beam is light and very portable. (You could put together a foldable antenna using fiberglass rods as spreaders that would break down into something you could throw into your trunk easily.) - Simple pvc pipe mast and so on...

Yes, a DB-420:

http://www.tessco.com/products/displayProductInfo.do?sku=73361

Even though it's speced for 450-470 MHz it works great down to at least 442. There has been a lot of business band systems turned down recently so you may find one cheap before it is sold for scrap.

You won't get a gain of that much with an omni directional antenna.

That one is fairly directional. Keep in mind that there is no "best" antenna.

Is everyone that needs to hit the repeater in one direction? Directional antennas will be sensitive in one direction primarily.

If you are doing a bike race that is cross country (well, perhaps cross county) - the roads will not all be a straight line.

Hi Dave..

For single band operation at vhf-uhf, it's very hard to beat the cost and efficiency of the ground plane antenna. All you really need are a so239 chassis connector and some stiff wire. Put a little loop, or solder and eyelet, in the vertical radiator and it can be hung up just about anywhere; a hose clamp around the connector will let you mount it on a pipe, plastic tube, or wood stick. I've not had any problems with "tuning" a ground plane, and have found it generally not necessary. The antenna seems to be mostly impervious to bad construction techniques.

<<http://www.ccars.org/projects/2mgp/tech_2mgp.htm>>

The above web page has directions for 2m, 220, and 440; the dimensions for 440 are pretty small.

You'll need some stiff wire and a soldering iron, but the antenna is quick and easy to make. Wire can be welding rod, coat hanger, or copper. If you have some heavier gauge copper wire around, strip the insulation off, then put one end in a vice and the other end in an electric drill; running the drill slowly will twist the wire, causing it to "grow" in diameter, shorten in length, and work harden. Makes for good antenna elements, if its not exposed to the weather and birds.

I have this controller which is hooked to a Ham IV rotator. The coin battery in the keyboard was bad and has been changed. The keyboard runs the rotator in each direction from the manual control okay. The keyboard screen works fine but the compass rose don't indicate azimuth. They do light up when the unit is initialized.

First question: does anyone have an operations manual for the controller? It acts like it's okay, just not getting the right sequence of keys.
Second question: Would anyone have a standard Hy-Gain controller for this rotator? I'd like to buy one and get this unit in the air.
Thanks & 73,
Pete Carr WW3O

antennas can heat bodily tissue and animal type tissue. the rf can actually cause burns to the skin but i doubt that the rf would heat wood type material. so a fire caused by an antenna would be very unlikely. only possible danger is power lines near an antenna whether in a tree or not.

On Thursday, January 9, 2014 6:58 PM, "kl7rs@..." <kl7rs@...> wrote:

Does anyone know if an antenna hidden in a tree can actually catch the
tree on fire?

What precautions if any can eliminate or reduce the
chance of this happening. I'm curious because a lot of people are living in HOAs these days and are forced to put up stealth antennas and I can only assume most of these stealth antennas are going up in trees.

I live in such an HOA / CC&R neighborhood and yes, I have three antennas strung through the trees. One is an 88 foot long doublet made with #26 "Silky Coat" wire I bought from The Wireman in SC.I run 500 watts to it on 40-6 meters from an Elecraft KPA500, through 110 feet of 450 ohm ladder line. I had to replace part of the wire several months ago because a limb broke and snapped it. Inspection of the entire 88 feet revealed ZERO punctures or arc-through spots. This antenna has been up for over three years and performs very well. It is almost 100% horizontal in orientation.

I have two other wire antennas, both Inverted L's. One is for 80 meters, the other is for 160 meters. Each runs vertically up the side of two different redwood trees and then over a limb and out horizontally. Neither of them have had any evidence of arcing. And lastly, none of my trees have yet to become roman candles! :-)

That being said, running 1,000 or 1,500 watts might be a different story, so YMMV!

Jim / W6JHB

It takes so little to set dry leaves ablaze! Probably the best thing I ever did is find an antenna that I could put away when I was done 'playing'. I got an EzMilitary antenna and it works great. Just google it!

I currently use full power on a 5 BTV Hustler vertical and two inverted V's. One inverted V for 80 meters and another for 18 meters in the pine woods behind my house. Before these antennae, I used a 5BTV all band inverted V in the woods for 15 years and have seen no indication of a anything getting hot or catching on fire.

For starters, I think you probably mean 1/2 wave dipole not a full wave dipole (the later would around 66 feet on each leg ...132' total ...mighty big house

"Work" is a relative term ...but yes it will work to some degree in either configuration. In fact given the other compromises that such an antenna presents I doubt seriously that you will be able to tell the difference in a meaningful way.

Contraire My Friend! You need to do a "little" homework. 1st...any live tree (has sap & moisture in the wood & bark,) can be ignited by an electrical arc. Depending on antenna type, (end fed, vertical, 1/4 wave, 1/2 wave, etc,) how it is fed (coax, ladder line,) fed (gamma match, stub, direct, etc,) AND the SWR of said antenna, determine's the Voltage & current nodes & where they are maximum & minimum.
2nd...I won't bore anyone with dry theory...but your statement that RF can't heat wood, or cause a fire is...well, false.
FYI- I was lax in trimming a tree close to a Hustler 6-BTV a few years back. I got lazy and moved about 30 KC from my sweet spot on 75 Meters with OUT touching up the tuner, (I was checking into a net at the time.) Within 3 minutes my neighbor called me on the phone to tell me my tree was smoking. (It was.) A few more minutes without tuning again...I would have had a fire. 1/4 wave Verticals have about 5,000 Volts at the tip-tuned, more if the SWR is high. And...NO! I was only running 110 watts at the time. (No amplifier on line.) Google it sometime. (1/4 wave vertical antennas and high voltage nodes).

I have a bunch of MFJ mobile antennas. None of the stainless steel whips are together with any of the fiberglass shafts. Now I'm trying to figure out which whips go with which shafts. If anyone has a MFJ 1640T (40 meter) or the (20 meter) mobile antenna, could you measure the stainless steel whip and let me know approximately how long it is so that I can get some of these matched up?

I meant to reply to the person asking about the attic antenna: be careful to keep the antenna away from wooden or other flammable objects, especially at the ends, and especially if you are running anything above QRP.

I had a fan dipole in my attic, and had the 40 meter elements folded at 90 degrees to fit. It worked OK, except for the fact that the attic had lots of metal objects, which probably absorbed much of the RF. But I did make contacts. I was careful to keep the antenna at least a foot away from any objects, using insulators and rope.

Hello. Forgive me for this "deer in the headlights" type question.
I have put a butternut vertical on a 10-ft mast (and I want to add another 10') using twinlead for elevated radials. Now I have this issue: the resonance points are generally outside the bands, and are all not where I want them. So I can take my antenna analyzer to the roof and fiddle around with the butternut, then with the lengths of the tuned radial segments and get it where I want it, then challenge the devil by adding another 10-feet to the mast.
OR
I can take down the butternut and put up a 43-foot vertical (no traps, etc) and put an automatic tuner at its base and ta-da, I'm done. Unless I fall off the roof (then I suppose I'm done too).

Finally, my question: what's the difference in effectiveness between using a resonant vertical vs an un-resonant vertical and a tuner at its base? (feedpoint)

please help this old man figure this out.
thanks, 73, Doug k7kw

Doug

1) My experience (B-nut user 30+ years) is the B-nut shouldn't change that much at 10' vs 20' above the ground

2) The thing with the B-nut is that because of the loading system (and 15M Decoupling stub) is that the part (with the exception 0f 10M) that radiates is actually a 1/4 wave or less which keeps the lion share of the radiation below approximately 30 degrees take off angle on ALL Bands. The 43' plain vertical will become longer than 5/8 wavelength on the 20M-10M bands resulting in the bulk of the radiated signal going up a very high radiation andngles warming the clouds but not useful for working even the east coast let alone DX from 7 land. .. 20M and below it will work better than the B-nut

Thanks Dave.
Clear description! So if radiation angle is the issue, then I suppose I could set up a shorter vertical for 20 meters and up, and use a tuner with it for those bands, and have a good match and good angle both.
There's a lot to learn about antennas for me. In the meantime, I will try an autotuner at the feedpoint of my butternut and take advantage of it's traps to keep the radiating element shorter than 5/8 ths on all bands, and still be able to load at off-resonant segments of the bands.

I owned the butternut hf6v when I first got started in ham radio and had it elevated and used the stub tuned verticals and did not have such a significant shift in resonance as you described.

I would double check the antenna to see if something happened to it when you moved it. One thing is for sure that it is a very sensitive bugger and once elevated I found shifting of resonance and interaction issues to be the norm. When the antenna works it is a great antenna but the constant adjusting and fixing drove me nuts.

At 5 watts , I would think about true (handmade) open wire feed line.On that long a run even insulaterd twin lead (300ohm TV line?) has enough loss that could make QRP a challenge

With QRP the higher bands (15M-10M) are more rewarding and forgiving than the lower bands. On 10-12 & 15 even dipoles at modest heights (20' masts) will likely be more useful than very long dipoles and wires. Possibly allowing the dipole to be paced closer to the shack (50' feed lines or less)

Cheers and welcome back

KF5ZYB

Due to your long 323 Ft feed run and desire for Multiband use it would be best for radiation efficiency to use ladder line as a feed for less loss as you stated. Then use an OCF Dipole. The OCF provides a higher impedance match point and is better for multiband. Lots on Off Center Feed (a.k.a. Windom) Dipoles split ratios vs. best band combination has been written and you can decide, but the 1/3 >>> 2/3 split is a good starting point.

Hi Doug,
I have read this post and the subsequent responses thus far and have a couple observations from using a roof mounted Butternut HF9V for a number of years.
The key to successful use of the Butternut HF6 and 9V verticals is that they require a great deal of care in tuning (great deal means a good solid day of work because of all the interaction between the various coils), and it is best done on the ground with the radiator just a few inches above a very good radial field for the ground plane, and you have to be at least 20 feet away from the antenna when you measure the results or they couple with the operator. They are also rather narrow in bandwidth when tuned, so a good external tuner is quite useful when running the edges of the tuned bands.
The aerial installation will require the ground plane radials to be installed in accord with the Butternut instructions for their kit (can be downloaded from Bencher's website), and as long as the ground plane is kept within the appropriate vertical distance of the base of the radiator the antenna will require little additional tuning at elevation as long as you have enough ground plane. When homebrewing the radial ground plane follow commonly accepted radial lengths for the bands in which you intend to operate, if they are too short you will be pushing a rope, and a tuner does not accommodate tuning the radial field.
One critical aspect of the Butternut HF6 and 9V verticals is the impact of winds on the antenna itself. They have enough wind resistance to be quite subject to knocking the capacitor ends out of the capacitors and also moving the coils around, therefore requiring significant maintenance to keep them properly tuned. I have to make at least four trips a year to the roof and repair/retune, but live in a very windy area. They also require guy lines to be installed on the radiator to keep them from breaking the aluminum tubing where it fits over the insulators on the vertical radiator itself (and even at that they crack the aluminum after a few years of wind storms in excess of 40 mph).
In my case, my Butternut is now one again rebuilt and setting in the corner of my shop, and I am installing a 56 foot homebrew vertical with a tuner at the base on a large metal roofed building. If that does not handle the winds, then I am looking to switch to a Zero-Five 6-80 meter Groundplane vertical on the shop roof and call it good until the next windstorm.

Hi Doug:

There are many opinions and prejudices for and against the 43-ft vertical. I think one of the most reasoned analysis is made by Phil Salas AD5X. Look at the following link:

http://www.ad5x.com/images/Presentations/Vertical43RevA.pdf

With regard to operation above 20-meters, Phil argues that the higher radiation resistance of 43 footer somewhat offsets the higher take off angles on the higher bands. Another approach is to offset (using nonconductive stand-offs) a smaller diameter conductor (wire or tubing) approximately 13 ft. long (~1/4 wavelength for 17 meters), and feed it in parallel with the main 43-ft. radiator. This "kit" is actually available from Zero-5, the maker of a very popular 43-ft. vertical.

I agree with Keith. I moved from the city and into the middle of Missouri. Tried several different antenna but the large delta loop beat all my other wire antennas. One antenna, coax fed with a 4:1 balun works all bands. I also have a long dipole, 160M size with a 80M fan, ladder line fed and it can work all band but 20 thru 10 the lobes are off the ends and not good broad side on the high frequencies. The delta loop is better.

Rich, Kd0zz

Subject: Re: [ham-antennas] new member with good Ant. challenge

If I had that I would do a loop. Many designs and great expertise here. Have fun and welcome to the hobby.

Depending on how high it is, a delta loop will work superbly... they just get very large and need to have a fairly tall tree (or set thereof) to hold either the pinnacle or tophat portion of the antenna. They are quiet, and generally work very well. An 80 meter would be a total wire length of 80 meters (minus the velocity factor) - but would be useful on 80 through 10 at least. Your height can be calculated based on a triagle.. with sides that are 1/3 of that 80 meters... around 80+ feet per side. So if your trees are sufficiently tall... and that is a big if... You may be able to do a corner fed, offset fed, or whatever. (I prefer feed at the top at the highest point if possible...)

Hi Doug,

Dave's right, there is nothing to prevent you from installing side wires for the bands that give high radiation angles. The pitfalls of the 43ft vertical are talked about here, with some models....

< http://www.hamradio.me/antennas/answer-to-everything-43-feet-antenna.html >

If you look at the mods done to a Hustler 4btv or 5btv trapped vertical for adding additional bands, you'll get the idea of what can be done. Normal mods add the 17 and 12 meter bands, but you could do 15 and 10m, too. 234/F(Mhz) would get you into a ballpark length. Input impedance should be about 35 to 60 ohms, depending on the radial field.

Helping out a new local here, He put up a 80 meter dipole, before this terrible winter hit, and hasn't been able to trim it to resonance on 80. It's slightly long.

He told me he uses a LDG auto tuner so he can use it on all bands.

He is feeding it with a 100 foot ready made piece of RG8X.

I began to think and told him we should change that out to some like 600 ohm open line. It would work much better for him. I was gonna run what his losses are with that current set up. Because of the losses of that small cable AND especially the added losses because of the should be HIGH SWR.

Ya know a 80 meter dipole on 40 meters should be really nasty true?

I asked him to get SWR numbers for each band without the tuner. He used a MFJ anilizer, and what numbers I was very surprised to read, as follows..

Coax <http://www.hamradio.com/detail.cfm?pid=H0-005876> is RG8Xmini. 100' as it came with factory PL59 ends already on it. I bought it when I was down at AES a while back and needed a ready-to-use coax run for temporary antenna arrangements and never changed it out to another coax.

I had the club analyzer for quite a while and hooked straight to the coax line w/o the tuner in line. I found the most resonant point on each band and here is what it is.....

10M: 2:1 @ 28.3MHz
12M: 2.2:1 @ 24.93 MHz
15M: 2.3:1 @ 21.275 MHz
17M: 2.2:1 @ 18.11 MHz
20M: 2.5:1 @ 14.225 MHz
40M: 2.5:1 @ 7.175 MHz
80M: 1.55:1 @ 3.8 MHz
160M: 1.7:1@1.955MHz

Part of my problem is that this is a home-brew wire dipole and I left the legs long so that I could trim them back to tune them. I was in a hurry to get this in the air before the snow flew last fall and I never trimmed it back at all. Shows what you get when you rush things I guess.

Actually those numbers to me look incredible for no tuner in line.

Or is the losses from that small cable hiding what is really happening here? Or is that MFJ machine junk?

Well if the antenna is very broad banded on those swr readings ie: swr doesn't change much from ssb to cw portion of the band, then that would indicate a substantial amount of loss in the antenna system. A 80 meter dipole fed with any balanced feed line will be a very good multi band antenna. I run one here with 300 ohm window line and works good. Just requires a big tuner even at a 100 watts.

There is nothing wrong with the 1.5 to 1 on 80 metres what are your expectations on a dipole.

Take some more reading every 1000 khz and give us more of a profile picture on each band

It should give you a dish shape profile.

Changing the coax length slightly may make a slight difference. what is your vf factor for the coax.

Read manufactures data of the coax jacket and look it up on the manufactures internet site

Remember your tuner is just satisfying the radio to make the antenna look like a 50 ohm load.

Have you cheked the mfj analyzer against a 50 ohm resistor to make sure its calibrated properly it shpud read 1:1

Remember your 2:1 swr means you could have an actual load of either 100 ohms or a load of 25 ohms either number give you a 2:1 number..

A dipole has a theoretical impedance of 75 ohms.

Good luck send us some more data to help figure out if your really too long

All band other than the fundimental of 80 are harmonics so.

yea all are harmonics of 80,

BUT..... a full wave dipole on 40 (1/2 wave on 80) should be almost
infinite SWR like 5000 ohms or some crazy high thing like that, NOT 2.5 to 1

Joe,

I missed the start if this thread. I've made OCF dipoles with a 4:1 current balun and had good swr on all harmonics. 80m, 40m 20m 15m and 10m. These are good antennas with low swr without the need of a tuner. Maybe something like this would suit better

It might change the resonance some .. and also keep in mind the dis-similar metals might need some attention to keep corrosion down ..

If it performed as well as an Archer dual band J-pole ... i might try this out .. and stick it on top of my MFJ-1798 !!!

Subject: [ham-antennas] Multi-Band dipole.

Helping out a new local here, He put up a 80 meter dipole, before this terrible winter hit, and hasn't been able to trim it to resonance on 80. It's slightly long.

He told me he uses a LDG auto tuner so he can use it on all bands.

He is feeding it with a 100 foot ready made piece of RG8X.

I began to think and told him we should change that out to some like 600 ohm open line. It would work much better for him. I was gonna run what his losses are with that current set up. Because of the losses of that small cable AND especially the added losses because of the should be HIGH SWR.

Ya know a 80 meter dipole on 40 meters should be really nasty true?

I asked him to get SWR numbers for each band without the tuner. He used a MFJ anilizer, and what numbers I was very surprised to read, as follows..

Coax is RG8Xmini. 100' as it came with factory PL59 ends already on it. I bought it when I was down at AES a while back and needed a ready-to-use coax run for temporary antenna arrangements and never changed it out to another coax.

I had the club analyzer for quite a while and hooked straight to the coax line w/o the tuner in line. I found the most resonant point on each band and here is what it is.....

10M: 2:1 @ 28.3MHz
12M: 2.2:1 @ 24.93 MHz
15M: 2.3:1 @ 21.275 MHz
17M: 2.2:1 @ 18.11 MHz
20M: 2.5:1 @ 14.225 MHz
40M: 2.5:1 @ 7.175 MHz
80M: 1.55:1 @ 3.8 MHz
160M: 1.7:1@1.955MHz

Part of my problem is that this is a home-brew wire dipole and I left the legs long so that I could trim them back to tune them. I was in a hurry to get this in the air before the snow flew last fall and I never trimmed it back at all. Shows what you get when you rush things I guess.

Actually those numbers to me look incredible for no tuner in line.

Or is the losses from that small cable hiding what is really happening here? Or is that MFJ machine junk?

Been in this since 1975 as a licenced Amateur, and sibce ohh 1965 or so
as a SWL. and i never had seen anything like this with a simple flat top
dipole cut for like the bottom of 80 meters.

The SWR on 40 and 160 should be pun intended "SKY HIGH!"

Converting it to a low loss doublet with balanced feed (and matching unit) would provide excellent results.... I played with one a co-worker put up in the trees outside his back yard. Even made his own feed line... Result? Plugged in my KX3, and at 8-10 watts got a good signal report from Brazil, and a 5x9 out of Delaware. (Both from the east coast side of the Carolinas.)

The antenna is up 60-80 feet in the air, and working superbly. (He was amazed at the coverage the KX 3 got off his doublet. --- If I could hear it, I could work it...and his doublet works very well... and is "too long" for 80 meters.

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

There is an excellent ham universe website that deals with dipole/doublet antennas, fed with balanced feedline, used in conjunction with a balun and a tuner. .I have used wire antennas for more than thirty years, tried most of them, and have had the most success with a simple wire antenna, and balanced feedline. The link below is a good read, and should help with your project(s)

I use a similar setup . 75 metre dipole at 30 ft fed with 50 ft of RG8
with an LDG Z100 autotuner and get good results from 75 metres to 6 metres . it is adjusted for approximately the centre of the general band . 3900 khz .

It remembers me a 80m dipole I built some decades ago. Low SWR on
every frequency I tested it. Amazing!
After some verification, it turns out the coaxial was completely
oxidized... :-(

Mike I'm using one right now. I built mine out of 1/2 inch copper and
with 3/4 inch PVC radome and my SWR using the dimension at N1GY's
website is less than 1.5:1 on 2 meters. I don't have a good meter for
440 so not sure of the SWR there but would gather it is also low. I have
it mounted at about 20 feet and the repeater I talk to regularly tells
me I come in full quieting and I'm almost 30 miles away in middle
Tennessee which is mountainous. I can also talk to repeaters in
Chattanooga which I can't with a 1/4 wave ground plane at the same height.
I think it is a really good performer.

SigWell If we are gona reminisse. I had a 10m Delta Loop. I matched with 1/4wave of Cable TV coax stub to a regular piece of RG8X about 25ft back to my upstairs shack. That antenna would present a reasonable SWR on 6m(the ssb portion) 10m 2:1 from about 283 to 28.5 and 12m 15m 20m and even 40m. Now it didnt get out well bellow 17m but showed a good swr. That aside I used a G5RV or Double Sized G5rv 204ft from many years before this qth and it worked great. BUT NOT without a tuner. Had one up in the California Desert it resonated on 1.820 1:1 but never got out worth a darn.

Subject: [ham-antennas] Multi-Band dipole.

Helping out a new local here, He put up a 80 meter dipole, before this terrible winter hit, and hasn't been able to trim it to resonance on 80. It's slightly long.

He told me he uses a LDG auto tuner so he can use it on all bands.

He is feeding it with a 100 foot ready made piece of RG8X.

I began to think and told him we should change that out to some like 600 ohm open line. It would work much better for him. I was gonna run what his losses are with that current set up. Because of the losses of that small cable AND especially the added losses because of the should be HIGH SWR.

Ya know a 80 meter dipole on 40 meters should be really nasty true?

I asked him to get SWR numbers for each band without the tuner. He used a MFJ anilizer, and what numbers I was very surprised to read, as follows..

Coax is RG8Xmini. 100' as it came with factory PL59 ends already on it. I bought it when I was down at AES a while back and needed a ready-to-use coax run for temporary antenna arrangements and never changed it out to another coax.

I had the club analyzer for quite a while and hooked straight to the coax line w/o the tuner in line. I found the most resonant point on each band and here is what it is.....

10M: 2:1 @ 28.3MHz
12M: 2.2:1 @ 24.93 MHz
15M: 2.3:1 @ 21.275 MHz
17M: 2.2:1 @ 18.11 MHz
20M: 2.5:1 @ 14.225 MHz
40M: 2.5:1 @ 7.175 MHz
80M: 1.55:1 @ 3.8 MHz
160M: 1.7:1@1.955MHz

Part of my problem is that this is a home-brew wire dipole and I left the legs long so that I could trim them back to tune them. I was in a hurry to get this in the air before the snow flew last fall and I never trimmed it back at all. Shows what you get when you rush things I guess.

Actually those numbers to me look incredible for no tuner in line.

Or is the losses from that small cable hiding what is really happening here? Or is that MFJ machine junk?

31297. Aluminum or steel conduit

Yahoo group: ham-antennas (2014)
Date: 2014-02-10 13:09:56 UTC
From: Richard Schmuke
Topic: 31279 Message: 31297

When copper hit its high a few years ago I made several J-poles out of conduit for some of our club members and they are still in use today. A couple strips of Lexan and a short piece of aluminum angle completed the assembly.

I'm actually in the pricess of planning an EMT conduit vertical myself.

Would there be less electrical resistance by using aluminum tubing? You bet, but you just can't beat the price of conduit, especially if you're just experimenting as I am.

From: Artek Manuals
Topic: 31279 Message: 31300

Initially you are only talking a few tenths of a db (if that) in additional losses with the EMT...the thing (not to forget) is that the EMT is more likely to have (noisy) joint conditions over the years than the aluminum..Periodic maintenance and /or bonding at the joints can pretty much avoid that.

I have a couple of J poles out of copper. This one☐s a giveaway.

The larger the diameter the better band width, ¾ EMT is cheaper.

I☐ll try it first

Steel here always gets a bad reputation. as being lossy etc.

it's much heavier, YES! But if it is soo bad a radiator, better tell
every AM broadcast station to take their antennas down because they wont
work because they are made of galvanized steel.

Nope, I used copper but I've seen people use EMT conduit also.

Hello joe

I am guessing that the lossy coax is making what is going on on the antenna side

I have a 34' 40M vertical I made out of EMT.
seems to work fine for me. and cheap.

and a 17' 20M vertical as well. Go for it.

Not much is said about emt, but for the cost and the fact it does work we can experiment around at low cost.

Steel here always gets a bad reputation. as being lossy etc.

it's much heavier, YES! But if it is soo bad a radiator, better tell every AM broadcast station to take their antennas down because they wont work because they are made of galvanized steel.

Would there be less electrical resistance by using aluminum tubing? You bet, but you just can't beat the price of conduit, especially if you're just experimenting as I am.

Or a bad connection on one leg, either at the antenna or the coax
connector itself, Just because it was "professionally" pre-assembled is
no guarantee it is good.

From: Richard Schmuke
Topic: 31279 Message: 31309

Hal , I agree with you 100%. Here are some pictures of my full size “portable” 40M antenna made with steel EMT used for field day.

http://s1102.photobucket.com/user/KD0ZZ/media/40M%20vertical/FeedPoint.jpg.html

I did receive some very negative replies when I first made it explaining that it was useless due to the poor conductivity of the galvanized steel. Our club had the last laugh because it worked fine. The green wires are of course the ground radials, the grey looking cable by the feline inspector are the guy wires used at the 20Ft mark where it changes from 1” EMT down to 3/4" EMT. The support structure and feed point are also shown.

31310. Re: AW: [ham-antennas] Multi-Band dipole.

Yahoo group: ham-antennas (2014)
Date: 2014-02-10 18:57:15 UTC
From: <soona4sail@...>
Topic: 31277 Message: 31310

I have come across several, so called, professional antennas, that come complete with dipole, balun and feedwire, Several that I investigated, had baluns of such poor quality, that it is a wonder the finals on the Xcvr did not blow on the first mike keying. In some cases, the "baluns" were not even baluns at all, just pure garbage. One particular balun, bought on the internet, described as a 4 to 1 balun, came in a sealed PVC tube and was listed at a special price of just $50. it did not work for my friend. I sawed it open, and discovered what he had paid for, was a 5 inch galvanized screw nail, with about 8 wraps of cheap coax. Not even a good RF choke, never mind a 4 to 1 balun. Other baluns I have seen, are extremely light duty, using very thin guage, poor quality, enamelled copper wire, tiny toroids, and questionable windings, that was probably good for 10 watts....maybe, and not the 300 watts advertised....They all had one thing in common....you could NOT look inside.

On the other side, it is unfair to those manufacturers, who do attempt to produce a quality product, and become tarred by this same brush.

I never buy anything I cannot look inside, and I always check with Elmers, and friends, to learn their recommendations. A balun is a very usefull antenna tool, enabling the operator to transition from a balanced to unbalanced line, but like anything else, the quality can vary drastically. Don,t skimp on your balun,.....it is an important part of many antenna systems.

31311. Re: [ham-antennas] Aluminum or steel conduit

Yahoo group: ham-antennas (2014)
Date: 2014-02-10 19:02:54 UTC
From: Chuck Schultz
Topic: 31279 Message: 31311
Attachments: 1 described; binary payloads are missing from this source WARC

*Several years ago at the Texhoma Hamaroma I purchased a 10/15/20 meter vertical for the sum of two dollars . The mount was broken and the source unknown.**I mended the mount with J B Weld and attached it to a 4 X 4 sheet of 3/4" plywood and hooked it up . Did pretty good but a little too simple so I added some spiraling wires on the plywood . This occupied my time for a day or two and it was cast aside. A week or so later while fishing and telling tales I mentioned it to an inactive ham fishing partner who expressed an interest in getting back on the air. After cleaning a mess of fish , I loaded this vertical into the back of the pickup with 50ft of coax and loaned this to my fishing partner . In a year he had worked DXCC on this thing . When mowing he would just pull it from place to place by the coax. Years later he upgraded to a Double Throw Down $400 vertical and returned my $2 antenna. He soon became inactive again , even gave up fishing . I still play with that antenna from time to time . Chuck Wq5B *

Well, correct me if I'm wrong, but because of the skin effect I think the steel itself isn't conducting much if anything at all. Instead, it's the galvanizing on the steel that is the RF conductor. That would also be the case of galvanized steel conduit. Here's what Belden has to say on that. Note they indicate microns as the thickness of the "skin" above certain frequencies.

http://www.belden.com/blog/broadcastav/Understanding-Skin-Effect-and-Frequency.cfm

Here's a table of properties of various metals. Silver of course is the best of all possible conductors. Zinc is two steps away from aluminum and steel is **way** down the list.

http://www.tibtech.com/conductivity.php

I don't think velocity factor has been mentioned yet in this thread, and if there' plenty of length to prune then the best length will be found empirically. In fact, I don't imagine one could find a reliable figure on the velocity factor of conduit, so one would have to experiment anyway.

I used copper form OCFD Vertical following N1GY's write up because I
wanted to solder the coax connection point so there wouldn't be a
problem in the future unless the coax broke. With aluminum tubing or EMT
conduit you would have to make a less than reliable mechanical
connection as Dave said.

Date: 2014-02-11 05:00:45 UTC
From: Geoff NW7GM
Topic: 31279 Message: 31318

With my vertical I'm planning on having my SGC-239 tuner @ the base in a weatherproof box that has the coax connector on it and a wire from that to the vertical. I'm thinking that the wire attachment will be a 10-32 screw all the way through the EMT and a wingnut + a star washer above and below a ring terminal that's been soldered to the wire. The wire itself is going to be 10AWG (pulled from an old furnace).

As for the vertical element, I'm probably going to split the end of each outer sleeved piece and use two stainless hose clamps per joint. I'll decide later if I'm going to do a through-bolt at the joints too.

From: Richard Schmuke
Topic: 31279 Message: 31319

Geoff, that is way I have my coax connected to my permanent 40M vertical at home with a 10/32 SS bolt. A 1" wooden dowel rod makes a good stiffing element between two length of 1" EMT. I have a small roll of silver plated wire I use for better conductivity, using conduit for support, I also have some of the silver plated wire for radials,.

http://i1102.photobucket.com/albums/g453/KD0ZZ/40M%20vertical/40MParts.jpg

http://s1102.photobucket.com/user/KD0ZZ/media/Multi%20Band%20Vert/MBVert004_zps6f68c326.jpg.html

For what it's worth K8JHR says my all band loop sounds better and is up one S unit then my vertical.

Thanks Richard. I may forego the dowel at this point but I may decide to put it in while I am in the construction phase.

" For what it's worth K8JHR says my all band loop sounds better and is up one S unit then my vertical."

How is that OM? Since he left the HRHG and I've all but stopped monitoring it, I haven't spoken with him. Next you speak to him, give him my best.

K8JHR calls a net for the TS-590 group some times. He is still the same, good information from him on audio. The other night we had a S9+ QSO before the net and he like my 80M size loop on 40 better than my full size vertical, 45 min later at net time the signals were down in the mud??? I will give him you best.

Rich, Kd0zz

Thanks Richard. I may forego the dowel at this point but I may decide to put it in while I am in the construction phase.

" For what it's worth K8JHR says my all band loop sounds better and is up one S unit then my vertical."

How is that OM? Since he left the HRHG and I've all but stopped monitoring it, I haven't spoken with him. Next you speak to him, give him my best.

Wonder how long that silver plating lasts out in the humid/ acid rain
environment? Since RF conduction is a function of "skin effect"
conductivity, I wonder has anyone done any comparative loss studies to
"bright shiny new" (copper, Silver, Aluminum etc) ...vs significantly
oxidized. Does your silver wire turn black after awhile?

Not surprising MO => MI is relatively short hop (500Mi) higher angle
path versus the vertical which is likely better for the 1500+ mile ,
lower angle stuff

31323. RE: [ham-antennas] Aluminum or steel conduit

Yahoo group: ham-antennas (2014)
Date: 2014-02-11 15:15:41 UTC
From: Scott Myers
Topic: 31279 Message: 31323

Like many hams, I've homebrewed all kinds of antennas. Some were purpose built with materials specifically bought for the purpose and others were made with junk I had lying around. I too have used pipe and EMT... and some steel as well, some NOT galvanized.

Right or wrong, what I have surmised over all the various attempts is that the material is not as important as I would have thought. I think the saving grace of lengths of materials is surface area. A particular material may not have the best RF conductivity, but if it has enough surface area for the skin effect, the RF resistance is still low.

In general, I'll still go with aluminum tubing for the strength to weight ratio, especially if I'm building something quite long. But it comes at a MUCH higher cost.

So go for it with the EMT! If it works, don't fix it!

73,

Scott AC8DE

From: William Collister
Topic: 31279 Message: 31325

Been pondering this issue, and having been an electrician in a former life, I suggest something for these joint bonding problems. Maybe try some NO-OX or similar product at the slip joints? That would possibly extend the electrical contact life at the junctions. It would also make disassembly easier at a future time.

The other possibility, but I don't really think it as THE answer, is the use of conduit bonding straps on each joint. It would, however, add maintenance and probably not be the best solution.

Subject: Re: [ham-antennas] Aluminum or steel conduit

With my vertical I'm planning on having my SGC-239 tuner @ the base in a weatherproof box that has the coax connector on it and a wire from that to the vertical. I'm thinking that the wire attachment will be a 10-32 screw all the way through the EMT and a wingnut + a star washer above and below a ring terminal that's been soldered to the wire. The wire itself is going to be 10AWG (pulled from an old furnace).

As for the vertical element, I'm probably going to split the end of each outer sleeved piece and use two stainless hose clamps per joint. I'll decide later if I'm going to do a through-bolt at the joints too.

I used copper form OCFD Vertical following N1GY's write up because I wanted to solder the coax connection point so there wouldn't be a problem in the future unless the coax broke. With aluminum tubing or EMT conduit you would have to make a less than reliable mechanical connection as Dave said.

With silver, it really doesn't matter: black silver oxide is still just as conductive and shiny silver.

I'll take your word for that for the moment.. so does silver oxide
behave like aluminum oxide in that it basically becomes a semi
protective barrier or is it more like rust which continues to "sluff
off" over time?

No. Aluminum oxide is an insulator, in addition to being harder than the hubs of hell. It makes an excellent abrasive.

> in that it basically becomes a semi
> protective barrier or is it more like rust which continues to "sluff

Well, I am certainly no expert on this, but I have never seen sliver oxide sluff off. It just gets blacker.

I know some metallurgists here and will immediately query my favorite one, Dr. Gene Bobeck, who has absolutely no connection to radio in any way, shape or form. He was the Chairman of the Metallurgy Department at the University of Idaho for a number of years, and was/is a researcher on it.

He will undoubtedly fill me in in excruciating detail. ;-)

Wait for it.

I don't seem to have any problem with my silver plated wire. It is 18ga , flexible, 19 strands, with a thin , .005 per side insulation that holds up for a few years in the weather. I have made everything from 2.5 Kw Tesla coil, a caged vertical and different dipoles and radials with it. I still have some to use. I plan to quit building when I run out of wire.

I would encourage you to put up a dipole with each leg extended as far as you can make it.
Hook up nearest the middle as you can reasonably get [I know you indicated OCF].
Run 450 ohm ladder line a convenient length [ex:40 ft, 80 ft] , but stay away from resonant lengths.
Get an appropriate tuner, auto or manual, and you "might" be able to get on 160-10 meters.

Well, just a suggestion. Best in your project.
James

yes, 1/3 / 2/3 works good with a 4:1 current balun. mine is for 160
thru 10 and is 180ft/90ft with a balundesigns.com 4114 balun but the old
MFJ seemed to work good too until it fell apart. some trimming may be
required to get it just where u want it. you can make it 90/45 for 80
or 45/23 for 40. the only band i have issues with is 30m where it
matches easily but not very efficient, 15 is not too efficient either
but works. I have sweeps of it if you would like to see them.

yes, 1/3 / 2/3 works good with a 4:1 current balun. mine is for 160 thru 10 and is 180ft/90ft with a balundesigns.com 4114 balun but the old MFJ seemed to work good too until it fell apart. some trimming may be required to get it just where u want it. you can make it 90/45 for 80 or 45/23 for 40. the only band i have issues with is 30m where it matches easily but not very efficient, 15 is not too efficient either but works. I have sweeps of it if you would like to see them.

31340. Re: [ham-antennas] Aluminum or steel conduit

Yahoo group: ham-antennas (2014)
Date: 2014-02-12 23:41:10 UTC
From: Harold
Topic: 31279 Message: 31340

Rich,
that looks good.

thanks for sending the info.

Mine is mounted on a deck around an above ground pool.

So all my radials are up from 2' to 8' above ground, around the deck structure. Also have my 20M vert also on the deck with raised ground.
4 raised radials for each vertical.

don't have any pics. snow covers them now.

Hal , I agree with you 100%. Here are some pictures of my full size “portable” 40M antenna made with steel EMT used for field day.

http://s1102.photobucket.com/user/KD0ZZ/media/40M%20vertical/FeedPoint.jpg.html

I did receive some very negative replies when I first made it explaining that it was useless due to the poor conductivity of the galvanized steel. Our club had the last laugh because it worked fine. The green wires are of course the ground radials, the grey looking cable by the feline inspector are the guy wires used at the 20Ft mark where it changes from 1” EMT down to 3/4" EMT. The support structure and feed point are also shown.

Rich, Kd0zz

Subject: Re: [ham-antennas] Aluminum or steel conduit

I have a 34' 40M vertical I made out of EMT.

seems to work fine for me. and cheap.

and a 17' 20M vertical as well. Go for it.

Not much is said about emt, but for the cost and the fact it does work we can experiment around at low cost.

Steel here always gets a bad reputation. as being lossy etc.

it's much heavier, YES! But if it is soo bad a radiator, better tell every AM broadcast station to take their antennas down because they wont work because they are made of galvanized steel.

I'm actually in the pricess of planning an EMT conduit vertical myself.

Would there be less electrical resistance by using aluminum tubing? You bet, but you just can't beat the price of conduit, especially if you're just experimenting as I am.

using 22- 1/8 “ and 15- 5/8 ” of ¾ “ aluminum tubing

Dose the material mater? Aluminum or steel conduit?

<http://www.n1gy.com/ocfd-dual-band-antenna-version-2.html>;

Nope, I used copper but I've seen people use EMT conduit also.

Hi folks, I'll be going thru a major home remodel this year and will not be able to use the shack or even be in the home. Should I try out a portable antenna such as Jerry Sevick's verticals or go with a mobile mount on the SUV? Either case would be fine as I'd park and operate, not actually driving.

I'll use my TS-590S, mostly on 40, 20, 15M and mostly DX and NTS and other nets, running barefoot with the on-board AT on the 590 if needed.

Primary goal is ease of setup, operating mostly in Colorado 4-Corners, some in California Bay Area.

I've looked at Buddipole but an easy homebrew would be preferable.

Thanks for any help.

Hi,

I'm in a similar situation. I use a mfj1979 with a homebrew raised mount. A m10 rod with a point grinded onto it. With a nylon plate at the top. With an 3/8 to so239 connector. Through the nylon. I use two elevated radials. The rod is only about 10 inches of the ground once pressed into the ground so have your threaded rod say 16 inches long. The two radials are 1/4 on 20m. You can adjust the antenna whip for each band or use your atu. I worked vr2 on 10w with this set up.

*I use an antenna called " Eagle One " on the back of my motor home and
I might suggest you look into it. Check it out on E-Ham for reports as
I did before I took a chance . I hmmmed and hawed for a year or more not
wanting to jump in the fire too quick . The kit is offered in several
mounting confs , I chose the RV ladder mount . It works as the claims
say it does, maybe better . It is easily installed on a tripod just
as the RV ladder . I found the tech support to be " A-OK " also
although all my questions came before my purchase
.....Google it up or look at E-Ham it may
work for you as it does for me . Chuck Wq5B*

Everything is in perspective .....He has apparently sold a
good number of these antennas so from his side it is a good business
. I would consider selling franchises to a small business I started
several years ago . I had invested in some dry oil wells in west Texas
and had little to show for my money. I ran an ad offering Pre-Dug holes
. I was offering them in four foot lengths so that they could be
easily shipped by UPS. At the time they only charged by weight so the
shipping was next to nothing . Packageing was also very easy .
The primary use for the Pre-Dug holes was to be used for the
installation of my Inverted Vertical Antennas I was developing for folks
in HOA's and apartments. I got off in another direction with my
interest making a million elsewhere but the opportunity is still there
for a younger more energetic aspiring millionaire. Chuck Wq5B

I'm winding down from a similar situation (been down since September). I'm not sure about the details of your project (whether your going to be doing the work our hiring it out), buy it may be that you really won't have the time you thought you would to dedicate to ham radio. Even though w farmed out the majority of work, we found we still had plenty to do (constantly checking on things and making sure the contractors did what they were supposed to). I truly wanted to get on the radio but I just didn't have the time or energy at the end of the day. I'll be setting my station back up in a few weeks. Your situation may be different, I'm just relaying what you may be in store for.

A far as the antenna, check out the 'H-pole'. Very easy to construct and seems to work well. I haven't built this one yet, but if the other vertical I'm going to be constructing doesn't work well, this is the next choice for me with a cobweb being the choice after that.

Selling a LOT of antennas, does not make a good antenna.

How many here bough the "Gotham Vertical" That was advertised forever in
all the radio magazines from the 60's and 70's?

No, but it might be considered " Good Business " by the depositor.
I am not interested in a business with or with out a good reputation.
I believe the one in question will require a very good sales person.

I actually offered the pre-dug holes 35 years ago on a two meter swap net in the Dallas area . I offered to send along the instructions for the Inverted Verticals with every order . I was a very new Ham and wanting to fit in plus have some laughs . I actually received a fair number of orders. I also had a Solar Simulator back in the Heat Wave of the late eighties. I was bragging of low elec bills with the use of my " Solar Simulator " . I would explain the 2 X 6 frame & black glass combined with bypassing the elec meter . I was contacted by a Professor & liberal wanting to assist me getting a Gov't Grant to research the thing . When told " I bypassed the meter " he cussed me out on the phone and hung up , then having more to say he picked up the mic and told everyone in two meter range what he thought . So much for my Solar Simulator business . I actually made a good living for years selling stuff that never belonged to me in the beginning. Chuck Wq5B EX Used Car Salesman

Not to mention the time to market the product. I once owned a business when I lived up in North Dakota (servicing CB radio systems –and no I did not “modify” or “adjust” the radios-just fixed either the antenna systems, power cords or whatever else was wrong). This in response to all the truckers in the area due the big oil boom going on. I know it took a lot of time not only to market the business but managing things (the paperwork), so I really didn’t have a lot of time to play radio. So Chuck is correct, any business, even a single owner, home based business takes a lot of time. Just my $0.02 worth of advice.

No, but it might be considered " Good Business " by the depositor. I am not interested in a business with or with out a good reputation. I believe the one in question will require a very good sales person. Chuck Wq5B

There are reviews for this antenna on E-Ham (under "Condo-buster), which anyone interested in buying this "business" should read.

31354. RV Antenna for fiberglass RV

Yahoo group: ham-antennas (2014)
Date: 2014-02-13 22:05:04 UTC
From: James M. Geidl
Topic: 31354 Message: 31354

I am looking at the idea of using a Jackkite pole with a wire up the middle for a vertical on my RV's ladder. This will put the top at about 30 feet and then add another 3-5 feet for the point of attachment on the bottom of the wire. For a counterpoise I am thinking about taking some 8 conductor flat cable, like rotator cable. and cut each segment down to resonance on the various bands. Everyone's thought are appreciated.

Jim, K6JMG

31355. Re: RV Antenna for fiberglass RV

From: Walt Haynes
Topic: 31354 Message: 31355

I have a similar setup (31' Jackite pole attached to RV travel trailer frame, short coax run to KX3/KXPA100 with internal tuners inside trailer), and have tried the following antennas.
1. 31' wire with LDG 4:1 unun at bottom, grounded to trailer frame. Results: non-resonant, but usable with tuners.
2. 31' wire with EARCHI matchbox at bottom. Results: same as 1.
3. LNR 10/20/40 TF EFHW with matchbox at bottom, inverted L configuration. Results: SNR<1.2 on 3 bands, great contacts, but limited to 10w for digital.
Since I had such good results with the LNR EFHW, and also with the 5 band EFHW from Hy End Fed antennas (at home QTH), I plan to try the Hy End Fed 3 (40, 20, 10) band EFHW, which should fit the RV setup, have good performance, and work at higher powers. It looks to also be usable on 15m.
I can get any of the above set up in a few minutes, none require radials (fit in small campsites and quickly), and none require tuners at antenna base (again simplifying setup).

31357. My Side of the story - Ham Radio Antenna Business For Sale

Yahoo group: ham-antennas (2014)
Date: 2014-02-14 18:46:32 UTC
From: Bill
Topic: 31357 Message: 31357

Reading over the comments, I found it interesting that none of the "naysayers" had ever tried the antenna.

The most realistic comment came from the gentleman in South Dakota who said the promoting a business was more difficult than developing it (or something to that effect). He was totally correct. And that is exactly what I am selling, the Name and the In-Place (turn key) Marketing for the product. Anybody can knock-off the product...and people have tried. But the trick is to successfully and cost effectively market the product.

As for quality, I sell an average of 500 antennas per year. That is approximately 5,000 in the past 10 years. Each and every antenna was sold with an absolute, unconditional money back guarantee..."If you don't like it I don't want you to keep it". Over the years received maybe 12 antennas returned for a refund.

I love the comments from the guy who sold the pre-drilled holes.

73s,
Bill

*I really appreciate getting honorable mention at the close of your post . Perhaps I could interest you in a couple of pre-dug holes . My business has sort of dried up . Chuck Wq5B Actually I read up on your enterprise when it was first advertised on QTH.com . Several years ago I supplied a few friends with some 4:1 baluns I had fabricated in my Tinker Shop. They were very pleased with them and told a few friends . The friends of friends requested a balun or two themselves . I began to think I should market said pieces at the next Hamfest . The proto types had been built with odds and ends found around a Tinker Shop , the production units would require a purchasing agent to procure the proper supplies . This was only a matter of changing caps. Soon I was tinkering and singing with thoughts of new found riches as I produced a dozen 4:1 baluns . Understand , I didn't design these, heck I didn't do anything but copy the plans from the internet just as anyone could have. The big day came and I set up a table in a choice spot to to market said baluns . After factoring the costs incurred by my purchasing agent by a paltry 2 to 1 ratio , I priced my units and prepared to negotiate prices . No one in this area pays retail , especially Hams . Here came the masses . Not a buyer in the crowd, nothing to barter about . I could make one of these myself said most . Had it not been for my junk box I would have been bust. I do carry a box of components salvaged from trash cans at previous Hamfests. I sell these for 25 cents each or 3 for a Dollar. At least half of this business ops for the 3 for a Dollar savings . People are wonderful creatures and never forget it . I still build a new Ham a wire antenna from time to time and furnish a Tinker Shop 4 : 1 balun

Bill, thank you for the mention at the top of your post. Only it was North (not South) Dakota. And I am now living in Colorado, where the business I owned would not have made it due to competition. But I have kept the idea in mind, and maybe, someday, might still own a business, but do not have the cash at the moment for investing. Both my wife and I are retired, with many medical problem, and a fixed income, otherwise, I would have jumped on your offer. Cheers and good luck.

I still have mine. Actually, it was a great way to learn about verticals and matching with minimal outlay. One of you talented writers needs to do an article revisiting the Gotham vertical and what it takes to have success with the few parts involved. You do realize that "Gotham" spells "Got Ham" don't you?

I do not know when you got yours.

But when I bought mine as a young freshman in High school and never
really bought much through the mail. It looked like a great deal.

A DX work the world antenna

For only 27 bucks! WOW

Boy did you get a surprise when a semi truck in from of your house
wanting 50 bucks for the "Railway Express" Shipping charges.

You pay it, peel the brown paper off and discover you just bought for 77
bucks a small coil, 4 conduit hangers, and a tube of aluminum, that you
could have gotten from a local supplier for 5 bucks.

Yeah great learning experience for sure.

Jim,

Sounds good. I mounted the LNR 10/20/40 TF EFHW using a Jackite pole mounted to the frame just behind the front hitch, with the trailing wire held up with kite string attached to the top of the rear ladder. I expect to be able to mount the Hy End Fed antenna in the same manner.

31365. coax balun orientation for 2m Yagi?

Yahoo group: ham-antennas (2014)
Date: 2014-02-16 18:29:24 UTC
From: <rob@...>
Topic: 31365 Message: 31365

I'm going to build a portable 4 element 2m Yagi using 5mm or 6mm O.D. aluminum rod and a PVC boom. I'm planning for a hairpin match and a 1/2 wavelength RG-8 balun (shield tied to feedline shield, center conductors tied to the feed points). Does the balun need to be kept away from or out of the plane of the elements, or can it be run down the mast or along the boom? I know that choke baluns are often used for these, but apparently result in a lot of loss.

Rob,

I wouldn't bother about a balun unless it really needed it. The loss from the balun is high on 2m

A friend here in town just did a 4 element quad for 2 meters, and it performs exceptionally well. Center tube is PVC pipe (1"?) and the spreaders are made of fiberglass driveway markers with a hole drilled for the wire.

His quad is rather directional, as expected. He's feeding it from the side (direct solder to the coax) -- with 6 turns of "ugly balun" just below the antenna on the pvd pipe that it is mounted on. It can be broken down and put in the back of an SUV in a matter of minutes, then be back up on a pvc pole just as quickly. He wants it up at 40 feet to talk to friends in South Carolina. (He's north of Raleigh) ... Even at about 15 feet, he can raise a number of repeaters outside the state. Lots of gain, easy to make, and great performance.

Walt,

Thanks. That Hy End Fed antenna looks like a possibility. Might have to
put a Jackite pole on the front and back to get enough length and just drape
the antenna over the two of them.

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

Subject: [ham-antennas] Re: RV Antenna for fiberglass RV

I have a similar setup (31' Jackite pole attached to RV travel trailer
frame, short coax run to KX3/KXPA100 with internal tuners inside trailer),
and have tried the following antennas.
1. 31' wire with LDG 4:1 unun at bottom, grounded to trailer frame. Results:
non-resonant, but usable with tuners.

2. 31' wire with EARCHI matchbox at bottom. Results: same as 1.
3. LNR 10/20/40 TF EFHW with matchbox at bottom, inverted L configuration. Results: SNR<1.2 on 3 bands, great contacts, but limited to 10w for digital.
Since I had such good results with
the LNR EFHW, and also with the 5 band
EFHW from Hy End Fed antennas (at home QTH), I plan to try the Hy End Fed 3 (40, 20, 10) band EFHW, which should fit the RV setup, have good performance, and work at higher powers. It looks to also be usable on 15m.
I can get any of the above set up in a few minutes, none require radials (fit in small campsites and quickly), and none require tuners at antenna base (again simplifying setup).

He got the design from a "how to" on You Tube.. I can easily get some pictures of it. (basically there are some small holes drives for the fiberglass at the locations for the various loops.. The length of the driven element is resonant somewhere around 146 (since he wants to hit repeaters.) - it is one of the diamond flavored loops, with the peak at the top, and driven from the side. Has a 1.3 or so at the bottom, up to about 1.6 at the top of the band. The reflector is about 5% larger...and the directors about 5% smaller. Mike indicated it was a *very* easy build. (Total costs were a couple of bucks for the PVC pipe (about 4' long) -- a PVC "T" which was glued to the support rod. The rest of the pipe got cut and force fit into the T for the boom. The loops are 14 gauge wire that goe from hole to hole.. and in the case of the directors and reflector are soldered to themselves. The driven element terminates both directions at the fiberglass
spreader, with the coax shield going to one side, and the center going to the other. The ugly balun was RG8x if (I remember correctly) wrapped around a 2" dowel (again, if I remember correctly). The wire was tied together, and dowel removed. The only connector added was where it plugs into his switch for the radio. It is VERY light, and can be turned by a TV antenna rotor with no problems.

Look at You Tube for the four element cubical quad construction video. You can see the s meter move when you make a 10-15 degree turn.

He has an antenna analyzer which helped with getting the length of the driven element dead on.

Yes, and I use the front mount for my hydraulic winch. With it mounted on the trailer tube, I can move the winch from the front to the back!!!!!! Great for raising and lowering tilt over towers using a ground mounted gin pole.....

Thanks for the input guys. I got the idea from the section on voltage baluns a bit over 1/2 way down the page at http://vk5ajl.com/projects/baluns.php http://vk5ajl.com/projects/baluns.php. It looks like he's got it on the boom of a folded dipole Yagi, but can't quite tell. I don't understand why it might be lossy, as it's basically feeding the two halves of the driven element with 180 degree out of phase RF, eliminating the balanced antenna/unbalance feed issue. Since I'd be using this almost exclusively with HTs when trying to reach terrain-challenged repeaters, I'm going to want to get as much power forward as possible. I've optimized the design for forward gain and SWR for that reason. Am I missing something? Seems like getting getting common mode RFI or introducing loss with an ugly balun wouldn't be good.

Yes he does.
I was under the understanding that the 1/2 wave length coax balun was a
better option for vhf and up.
If you use that balun and as short a good *quality* coax that you can
you should have minimal loss.

I asked mike to send me some pictures and the video he went to for the design.

I asked - his does not break apart, but is sized to easily fit in the storage area of his RV. Thought it came apart, but he wanted "simple" and cheap. And it is both. I think he spent about $15 total on it, and used wire left over from a home improvement project. He even left the scotchbrite banding on the fiberglass, so it glows at night when hit by light. <G>

Hi, looking for info on how to wind a 2.5:1 air core balun for a single band loop antenna, I have read lots of arguments about these things but would like to try one against my 4:1 toroid balun out of interest, there is a guy in the USA who sells them and is getting good reviews but for the price of a plastic tube former and some wire it would not be cost effective to ship one over here to the UK. Does anybody on this forum have any information on these balun's or a link to a site that does have the construction details please.
Here is the link to the builder of the USA version I am interested in reproducing to try .http://www.qrz.com/db/AG6IF sorry if this should be put in another section.
cheers
Phil M6MRP

Phil,

I made one using a toroid. It worked well for single band antenna. I used a 4/1 for multiband use age which worked well. I've never made an air core version but the toroid version will be easy enough to make.

Hi Billy, I have got the plans for the toroid 2.5:1 balun/transformer and also noticed they are now being produced by balundesigns after many requests:-
http://www.balundesigns.com/servlet/the-121/2.5-cln-1-balun-125-dsh-50-ohms/Detail
http://www.balundesigns.com/servlet/the-121/2.5-cln-1-balun-125-dsh-50-ohms/Detail
Personally I am a big fan of loops and a balun that gives me a closer match to 50 ohms can only be better, after trying a 4:1 air core on another wire antenna I use and getting good results I really want to try the 2.5:1 air core on a loop just out of interest, as I have said for the price of a plastic tube former and some old wire it cant do any harm and it will keep me occupied and out of the xyl's way for a while.
Somebody on here must have wound one before?

Phil

Richard don't buy a subscription to CQ Magazine. They are having financial problems and shipping the print version of CQ erratically, late to very late or not at all.

I bought a subscription on November 4, 2013 and have yet to receive my first issue. I contacted them by email on December 5, 2013 about the issue and they told me that the first issue would arrive at the beginning of January 2014.

Well it's February 19th and still no first issue and they have not responded to my latest email query sent in on January 15th..

When things were $$$ okay for them CQ magazine was the better magazine as compared to QST. I found QST to be boring and stale.

Well, their website has the digital versions of January and February online to read. As most are probably already aware, CQ is changing a number of things. Here's the scrolling banner at the top of their homepage:

Popular Communications, WorldRadio Online and CQ VHF to merge with CQ as of February issue.

I suspect that *if* they are having financial issues, effectively eliminating three of their magazines should go a long way. The merging of magazines is not uncommon, but one of them is the dominant one and the other ends up being reduced to a monthly column. I suspect we will begin to see a monthly column on monitors, one on SWL, and one on VHF.

Richard;
I have (almost complete) both QST and CQ going back to 2000. To you, (or anyone else, for that matter) I would love to find another bookcase home to. I am sure there are some missing issues here or there, but they are free, but they would have to foot the postage (UPS would be best). To those having problems with CQ, please "bump" them again. Without fail, CQ comes one day, followed by qst the very next day.
My shipping address would be: 49201, and would suspect they weigh in at about 50-60 pounds

I built a cobweb for its pattern being nice and circular and at 40 ft high it works great.

I am not space limited but it is out performing my fan dipole inverted V (35 ft) and my big loop. If I hear them I work them and this antenna hears real well. I don’t know if its due to polarization but it has a nice signal to noise performance.

I have not owned a beam antenna yet, but if you don’t want to deal with a rotor and so on it’s a good antenna and does not appear to be a compromise.

Subject: Re: [ham-antennas] Best Antenna For Small Backyard?

The only problem with a hex or spider beam is you need a rotator. With a cobweb antenna, you don't. I do agree with the remote tuner (ah4 or sgc model) if you end up doing a wire antenna.

For the best information on antennas, you'll get it right here. I'm not a moderator, list owner, or vendor but most of the information here will be well intended. I like the magazines but their mission is to sell advertising and you may not get a brutally truthful review. Like wise, there are other forums that have good information. Check out the ones on your particular rig. Thanks to the list owners for providing this service.

I don't know much about ham-related magazines....

However I hear many people love QRP Quarterly. QRP folks tend to be more hobby oriented, so maybe that's a way to go if you like homebrew projects.

So it all depends on your interests.

This is one reason that I no longer subscribe to any magazine for more than one year, no matter how good the deal is.
Since about the mid-80s, any number of magazines have ceased publication. Byte Magazine comes to mind.

The XYL paid for a lifetime membership to World Radio. We both enjoyed it. But that was before they ceased publication the *first* time.
Supposedly she got a subscription to CQ Magazine equivalent to the money that remained, but not a lifetime subscription.

My only regret was not getting a life membership to ARRL years ago.
I was angry with them over Incentive Licensing, since it caused me to lose privileges that I had earned already and was using, and so I stayed away for 30 years.

Jim....
I have the same feelings toward the ARRL as you do. I was in grade school when I got my Novice ticket and only in sixth grade when I got my General. I didn't understand most of the theory I "learned" but I was able to pass the test. Then, in their infinite wisdom pushed for Incentive Licensing and like many others lost those
precious lower portions of the bands. Now it's almost a joke the way the tests are conducted.... if you have a good memory you can just about pass the Extra without a problem and you really don't need to know the theory. The days of my memorizing a lot of stuff I fear is long past and I will just have to stay with my General. Hope I don't get "flamed" for this!

Francis: GA OM...I just have to respond to your text. I feel sorry for all the new hams, (and our fraternity,) that never had to go before the steely eyed FCC inspector and take THE code test..before even being allowed to look at the written. (Those guy's WERE the original "men in black!") I was NOT for incentive licensing-back in the day. And I was (still am,) AGAINST the no code license...and always will be. However, our hobby was slowly dying. We couldn't compete with computers & video games, kid's were slowly introduced to the "no kid can fail" instant gradification the left winger's have made the norm now in the USA. AND we have a lot of RF spectrum that a lot of people wanted for monetary reasons. IF the ARRL had NOT pushed for the path they chose...I fear the hobby would be a shadow of what it is today. Like the American Indian's...we would be operating on 2 or 3 bands with a small spectrum to use. WE would be on OUR "reservation!" I give the ARRL credit for that. I would love to support the ARRL, but their policy of having to pay for & take QST doesn't make me happy. For those of us on fixed income, (retired-on disability now. ONE bullet to many.) I wish they would make an option to be a member at a reduced rate-WITHOUT having to support QST. But I don't see it happening.
And...your right! The hams today are basically just "appliance" operators. I listen to some of the VERY basic questions they ask & talk about on the air...and wonder IF the had an elmer? I am getting old, and I know times change. But I DO long for the ham radio I knew in the mid 70's-when I got started. The GENTLEMEN and ambassadors of the air waves we were then. Granted we had our "dark side" (the guys on 80 meters at night)-the ones you NEVER wanted any visitor to the shack to "hear" when you were trying to get them interested in the hobby. But then again I never had to walk to school 5 miles, in the snow, up hill...like my Dad did. Point being, we all remember the fond memories of the past, and wish it could always be like Mayberry, (remember the double digit inflation we had for 4 years with President Carter?) Things will never be like they were.
I see a LOT of Extra's today that can't solder a coax connector on right. And my 4 year old grandson has more electrical knowledge then most of them. Remember when you had to be a ham for 2 years before you could even smell the Extra test? What the hell happened to OUR hobby?
Now..you walk into a VE test site, pay your money, take a memorized test...and CAN walk out with a license...and NEVER have made a contact on the air! I just feel we went in the wrong direction with our hobby. But maybe we had no choice. At least we still have our bands to "work them" on.
PS..the 4 land call comes from my years as a Florida Deputy Sheriff. Back in the day (for you newbies,) when you moved from one call region to another you HAD to change your call-to the number of the region you moved to. Yes! you lost your vanity or special call...and had to take your chance's on a new one being available that YOU "liked." It was called adversity..you had to adapt and deal with it. Something we have forgot how to do in today's me, Me, ME world in the USA.

I'll put my soapbox away now...thanks for the memories! (Now I will go put my asbestos underwear on...(for the flames too come!)

73,

Dave-KJ4PF (Ex-WB3KNS) 38+ years as a ham..and finally having the TIME to enjoy the hobby!

Jim....
I have the same feelings toward the ARRL as you do. I was in grade school when I got my Novice ticket and only in sixth grade when I got my General. I didn't understand most of the theory I "learned" but I was able to pass the test. Then, in their infinite wisdom pushed for Incentive Licensing and like many others lost those
precious lower portions of the bands. Now it's almost a joke the way the tests are conducted.... if you have a good memory you can just about pass the Extra without a problem and you really don't need to know the theory. The days of my memorizing a lot of stuff I fear is long past and I will just have to stay with my General. Hope I don't get "flamed" for this!

All, Just moved and looking to rebuild my station. I plan on mounting the antenna on the roof of my detached garage. Garage ends right in the property line and I have about 10-15 feet of clearance from the peak of the roof before I'm in the neighbors yard. I want something directional with 40meters. Ma5b would be the perfect size but no 40meters. So I'm thinking of the comet h 422 rotatable dipole. Am I wasting my money, is it junk? I know I'm compromising but I'm a severely compromising? Thoughts or ideas? Thanks, Doug KB2UKA

Gentlemen, I just have to respond to this from the other end of the spectrum (pun intended).
I passed my tech several years ago and became a general two years ago. I am an electrical engineer so the only difficult portion of the tests for me were the rules, regulations, and exposure limits.
The point I wanted to make is that I am glad they eliminated the code portion of the exam. I have some interest in code, but why should I have to take a special test on just one operational mode? Since there are so many operational modes today, and quite a few hams will never use them all, why have them test on just one?
Now I am not for making the exams overly easy. There are several things that should be understood before someone gets their license. But my point is, maybe someone wants to build a microcontroller (arduino) based SDR and do APRS. Why should they be forced to learn a mode that they should never use. Or conversely, lets make "practical" tests for all modes and/or more aspects of the test. For example, maybe a prospect has to demonstrate the calculations and actually build a dipole, or solder/crimp a connector, copy a weak ssb signal, decode a digital signal..... and the elmer/examiner checks these things off like we did when we got our boy scout merit badges.

Basically, I agree that the tests are very easy, and probably should be changed a little, but being tested on just one mode of operation seems silly to me.

Hello everyone/anyone, my name is Terry. I have an antenna issue that needs attention however I do not really know how to resolve it, may I run it past you and if you have any suggestions I would love to hear them.

I operate a Yaesu FT 757GX with a 757AT tuner and they are connected to a G5RV that I bought last year at a local hamfest. During the year the line Isolator (mfg. label I believe it was a balun located at the end of the flat line) became water filled and caused problems. After researching the internet I learned I could homebrew an air core balun using 10-11 turns of coax turned on PVC pipe and use this to replace the original isolator/balun. I did and have only experienced problems.

my rig is 100watts output but only giving 10watts per my tuner P/O meter. radio P/0 meter is set for rev power and shows around 80watts being reflected. SWR is <1.5:1 on 20meters <3:1 on 40&80 meters with radio connected to a dummy load tuner power output is 80-90 watts and 0 on the radio P/O meter so the rig looks good. flatline matching section is +/-34' long and 450 ohm ladder line feedline is RG8X +/-20' long to the radio room Antenna center is 36' high and is operated as a dipole
I feel the problem is with the homebrew balun but I do not know what to replace it with? Or, Should I replace the entire antenna rig with something else. This was my first Hf setup after upgrading my licenses, I didn't have anyone to talk with or ask advice, it was self research all the way.

Thanks for your time
Terry

Just thought I would mention "Nuts & Volts". While not primarily a radio magazine it is filled with projects, many of which focus on microcontrollers and board level computers. You may also look at "Make" magazine or the website www.instructables.com. http://www.instructables.com. These again are not primarily ham radio directed but you can find radio related projects in both.

And even if it isn't radio related, you will find some cool project to give you an excuse to tinker at your bench or in your garage, man cave, or mad scientist lair.....

Hi Dave,

I agree with your statement below.
I didn't take " (retired-on disability now. ONE bullet to many.) "
I am disabled retired from one to many exposures to items used in the construction and maintenance of our highway system, My lungs gave up for the most part.
ARRL does need our support BUT being disabled early and on a retirement income now (No GOLDEN Parachute) I can not afford to support them since you have to have QST!
I manage about every 2 or 3 years to join for a year but that is it.

I think there would be more members in ARRL if it separated the Magazine from membership.
I also agree that the code should be part of it but see and agree why the change, I passed it way back in 1963 but dropped out for almost 40 years when life got in the way.

72/73
Adrian KF7DYU

<Snip>
I give the ARRL credit for that. I would love to support the ARRL, but their policy of having to pay for & take QST doesn't make me happy. For those of us on fixed income,
(retired-on disability now. ONE bullet to many.) I wish they would make an option to be a member at a reduced rate-WITHOUT having to support QST. But I don't see it happening.

Hi Albert,

The point "I" want to make is that the code is very necessary in that when *TSHTF* you can count on code making it through when "*noise is so high you can't *understand what is being said.
Also a pulse signal has way more *POWER* that a SSB, AM, FM or any other type of signal.

That is why there should be a Code requirement for ANY radio license including *Chicken Band & FRS!*

I better find some asbestos and Kevlar armor now.

Ok i will try to give you some info and help:

The g5rv is a extended dipole for 20m (reason why swr is around 1.5)

It "CAN" be used on other bands with a wideband tuner (but with a bit of higher loss)

Your 757at is not such a wideband tuner ... it is only build to tune below 1:3 (so a resonant dipole at the band edges or similar)

I would route ladderline completely down to the shack

And the use a manual tuner with built-in balun (or a homebrewed balun connected directly after tuner)

Ok ... you do not wanna buy another tuner??

Then maybe a fan dipole would be an option

That is resonant on as many bands as you add dipoles to it

But pruning is a lot of work till all bands match

(start with lowest band first ... do not cut the ends but bend backwards and wrap around the end so you can again make it longer without soldering)

Or maybe a trap-dipole???

Several ways to skin that cat hihi

Greetuz

Sigi

Dg9bfc

Ps ... look for some good antenna books (like the arrl antenna book) ... go to your local hamclub and ask an elmer for help ... ask on local repeater if anybody is willing to help you with the first steps

First thing I would suggest is to now put the dummy load @ end of the coax both with and without the tuner attached and test again. Let's at least alleviate the possibility of the coax being at least part of the problem. Then the tuner, as well. Realize that the tuner at the feed end of the coax only "makes" the antenna system look OK to the radio, it really doesn't "tune" the antenna (it's more of a match-box). To do that, the tuner would have to be placed after the unbalanced (coax) line and before the balanced line (you called it flat line) where it could then react with the antenna itself, i.e. an antenna coupler. Good luck!

From: K7Max
Topic: 31423 Message: 31423

I need to know (without climbing the tower) what the bolt and thread size is for the top section “set screw” of a Rohn 25G. The Rohn specs identifies it as a “set screw” but it is actually a square or hex bolt welded to the top feed thru section. It is used to lock a fixed antenna mast to prevent turning in the wind.

Due to health reasons I can not climb anymore but I have a neighbor who has been climbing for me. I need to raise my hex beam/mast so that I can remove a Yaesu G450 rotor for repair or replacement. In order to do this I need to insert the correct size bolt to lock the mast. Next to last photo on http://qrz.com/db/K7MAX shows the Hex on a short side mounted Rohn 25.

Thanks in advance.

My understanding is that coiled coax balun is for rf not voltage
I suggest that you replace the original balun with one of the same specification

These baluns are there to alter the antenna apparent resistance
Dipoles do not have 50 ohms they are I believe around 75
However when folded and modified as a G5rv this could be much higher and the correct balun is required

Hi, Terry,

Others have given some good advice. I'll just add a few points.

The G5RV is not designed to have a balun; it uses the 34' ladder line as a matching transformer. The original G5RV had the coax directly connected to the ladder line. What you have used there is technically not a balun, but a common-mode choke. It won't effect SWR, only common-mode current.

I use the wire from a G5RV (102 feet fed in the center) with a long run of 450-ohm window line to a 9:1 balun, then through 3 feet of coax to a wide-range tuner (MFJ-998). It loads up well on all bands from 80 to 6, with the most trouble on 15. (I now have a five-band Yagi, so I only use the doublet on 80 to 30.) I got basically the same result with a 4:1 balun, and picked the 9:1 because it was easier to mount on the 4 X 4 post outside the shack. I can also use the doublet on 160 by shorting the near ends of the window line together and loading it against some ground radials. Works OK.

I'd recommend a real balun at the end of the window line, as near to the tuner as you can get it. Use a wide-range tuner, and you'll be good to go. The window line has lower loss than coax, so a high SWR on the antenna isn't much of a problem, as long as your tuner can handle it (which, of course, the internal tuner on your rig can't).

Hope that helps.

73,
Frank

From: <the_melzer@...>
Topic: 31383 Message: 31426

When I was first licensed back in 1961 I had to go to a notary public and swear an oath of allegiance to the United States. Ham radio has changed an awful lot since then. Most of the newer radios would be difficult for most competent technicians to repair, let alone the average guy that would only work on them occasionally. How many among us are comfortable working with SMDs? Who has the equipment to do it without ruining the board they are mounted on. With computerization, would any of us stand a chance understanding how a radio worked without being versed both in electronics and computer science? If you can't see what the program the processor is running looks like it falls into the realm of magic.

You have to use halfwave length of ladderline (or multiple of that) if you
wanna have a resonant system (only that is tune-able with your 757at)

And you have to make your dipole resonant on the band of interest

As I already said (wrote) ... your tuner can not handle a great mismatch

I would agree with that.

> flatline matching section is +/-34' long and 450 ohm ladder line

I assume when you use the term "flatline" you MEAN the 450 ohm ladder line. Am
I correct?

> feedline
> is RG8X +/-20' long to the radio room Antenna center is 36' high and is
> operated as a dipole I feel the problem is with the homebrew balun but I do not

First of all, as someone else pointed out, that homebrew job is not a balun: it
is a common-mode choke, and I doubt that that is the problem.

> Or, Should I replace the entire antenna rig with
> something else. This was my first Hf setup after upgrading my licenses, I
> didn't have anyone to talk with or ask advice, it was self research all the

Most of us have been doing it that way for many years. At least I know I have.

Now, as someone else said, move your dummy load to the FAR end of the coax, and
take some more readings.

At this point, I suspect that the coax got water in it or is otherwise bad.

I think all other points have been pretty well covered.

The Diamond V2000 was designed for use with the Yaesu FT 8900R transceiver.
It will operate on the FM portion of all 3 bands with less then 2:1 VSWR.
It is shorter then the Diamond X500 series and more versitile - does 3 bands.

I tried it with a old Radio Shack HTX 202 handheld radio and it was folding back enough that the HTX did not like it. I would say that it is the one basic solution for anyone wanting to do local comm's with a all in one antenna and a Yaesu 8900R..
No - it is not a beam antenna, but my experience with it has been adequate - making contacts up to 120 Miles away when the bands are open on 2 meters and making regular contacts up to 65 air miles away to repeaters in Western Pennsylvania - in challenging terrain to say the least.

The only experience I have had with the Comet was at a friends shack - it was a different location, I was not impressed with the Comets performance. I wouldn't turn down a free Comet, but I wouldn't buy one....
Communications is all about location, location, location.....l

Topic: 31205 Message: 31430

Your SWR is affected by the close proximity of the roof.
The whip is only for 6 meters, everything else is done with the radials on the side of the antenna.
2:1 is just fine for local work on the FM repeaters.

The Diamond Discone is more of a FM communications type antenna - good for public service radio - high VHF / 450 - 470 MHZ.

If the SWR is low at 145.000 MHz and is high at 148.00 - that would mean that the 2 meter radials were too long..
There should be like at least two - long radials - those are for the two meters side I believe. I wouldn't cut any of them...

Mount the antenna outside, and as far away from other antenna's and metallic objects in the neighborhood and try it again!

If I understand the comments on "radials" below, there is a misunderstanding of what those elements are. They are not 2 meter radials. They are an important part of the discone design and are important for all frequencies above the lowest design frequency. Don't cut anything off of them.

Ray, W4BYG

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Rohn 25G tower question

I need to know (without climbing the tower) what the bolt and thread size is for the top section “set screw” of a Rohn 25G. The Rohn specs identifies it as a “set screw” but it is actually a square or hex bolt welded to the top feed thru section. It is used to lock a fixed antenna mast to prevent turning in the wind.

Due to health reasons I can not climb anymore but I have a neighbor who has been climbing for me. I need to raise my hex beam/mast so that I can remove a Yaesu G450 rotor for repair or replacement. In order to do this I need to insert the correct size bolt to lock the mast. Next to last photo on http://qrz.com/db/K7MAX shows the Hex on a short side mounted Rohn 25.

Thanks in advance.

So PSK31 or RTTY won't do just as well as Morse Code???
I beg to differ and even though I got my extra by passing the code test
I for one don't see why CW wasn't dropped long before it was.
I seem to remember reading somewhere that we (Amateurs) were the last to
drop that requirement for getting a license.

Can you "decode" PSK31 and/or RTTY in your head?

I doubt it.

All those "other" digital modes require non-human intervention in order to be of any use whatever.

MOST require a computer, which requires at least as much, if not more, power than a QRP CW rig. Ever seen an SMK-1? I have one. About the size of a pack of cigarettes. Works great on 8 AAA cells.

You are, quite simply, wrong.

PSK31 doesn't need a computer.
< http://www.nue-psk.com/doc/NUE-PSKarticle(A4).pdf >
< http://www.nue-psk.com/ >

I got news my point is that PSK31 and RTTY will get through the noise
and needs very litte power just like CW.
I have decoded PSK31 with almost no signal.
I could barely hear the phase shift in my speaker but my computer was
picking up the signal anyway.

I Beg to differ

"...doesn't need a computer..."

OK. That means you can listen to a PSK31 signal and "read" it by ear/brain? Or a RTTY signal? Gee! That's impressive!

> I got news my point is that PSK31 and RTTY will get through the noise

Not so much, in my experience....

> and needs very litte power just like CW.

I would agree, somewhat, concerning PSK31, but most definitely not RTTY. Its bandwidth is at least 17 times a decent CW signal, 170 Hz vs 10 Hz, and every RTTYer I have ever heard about runs well over QRP levels of power.

Most don't run as little as 170 Hz shift either. Whenever the RTTYers have their bi-weekly "contests" the rest of us just shut our rigs off and go read a book because they completely clobber the entire digital spectrum.

> I have decoded PSK31 with almost no signal.
> I could barely hear the phase shift in my speaker but my computer

"...but my computer...."

So which is it? Needs or doesn't need?

> was
> picking up the signal anyway.

Uh, huh....

> I Beg to differ

About what?

Sorry, you just proved my point. You cannot use either PSK31 or RTTY (or any other "other" digital mode, for that matter) without some sort of non-human intervention for the purposes of translation.

I contend that you're wrong, and that you've just proved my contention.

I further contend that CW will always have a use because it can get through when nothing else can, and with an absolute minimum of equipment and power to boot.

BTW, have you ever watched the movie "Independence Day" ? Hee hee! :-)

That's not quite true about RTTY. You can recognize words and calls, but it takes a lot more practise than CW.

You have bandwidth and shift confused, two entirely different actions.

Timewave used to make a neat dual audio DSP that allowed you to
center one on Mark and the other on Space. You could narrow them
both down to 50Hz. In fact, guys could hold CW Q's in between and
they would never bother you.

I didn't say it couldn't be done: I said I doubt that he could do it. I know I can't...yet.

In fact, Bill Smith W7GHT who died recently in Boise, Idaho, during WWII taught Army radio ops to "read" 60 WPM RTTY and refused to graduate them until they could.

I think his top speed at copying CW was around 100 WPM. He used a mill. I know it was impossible for me to send too fast for him to copy 100%, and I tried.

Not actions: parameters. Yes.

> Timewave used to make a neat dual audio DSP that allowed you to
> center one on Mark and the other on Space. You could narrow them
> both down to 50Hz.

Which is still 5 times wider, for each, than a single CW signal. So 50 Hz + 50 Hz = 100 Hz, and 120 Hz left over for 10 CW signals between them at 170 Hz shift...or 5 at 110Hz shift.

> In fact, guys could hold CW Q's in between and
> they would never bother you.

OK,. but the ultimate bandwidth was still that which BOTH the mark and space take up, plus the "band" between them. Besides, name me more than one RTTYer who would have made it possible for a CW station to hold a QSO in between his mark and space, unless it had been pre-arranged.

In the case of 110 Hz shift, that would be 50 Hz (25 on each end) plus 110 Hz (between their centers) = 135 Hz bandwidth for a 110 Hz-shift RTTY signal.

BTW, I thought this forum was about antennas...

31449. Bandwidth defined.

Yahoo group: ham-antennas (2014)
Date: 2014-02-25 07:03:47 UTC
From: Kenneth G. Gordon
Topic: 31449 Message: 31449

According to the ITU, the "Necessary Bandwidth" for a 60 or 66 WPM RTTY signal at "100% duty cycle" is 270Hz. at 170 Hz. shift.

According to W8JI (whose definition of bandwidth is somewhat....unusual) "The bandwidth of a typical CW signal depends (soley) on the shape of the keying waveform"

Neither one of these "definitions" are completely satisfactory to me.

Now, to return to your regularly scheduled program: Ham Antennas!

Then they don't know what there doing.
I used RTTY in the Army back before they remove RATT rigs from service
(which was after I got out) and we didn't use that much spectrum.

>> I have decoded PSK31 with almost no signal.

Never said it didn't need some form of intervention. Just because I can
hear the phase shift doesn't mean I was trying to understand it.

Never said CW didn't have it's place. My point is there are other modes
that work just as well.
There are a lot of modes for any Amateur to choose from.
So I have to agree why test for one mode to be able to get a license.

Of course the above is mute considering we don't anymore.
I"m not a CW guy so it doesn't matter to me but doesn't mean I don't
know the code.
And even if I didn't know the code that makes me a lesser ham?????

31455. No Subject Headers ...

Yahoo group: ham-antennas (2014)
Date: 2014-02-25 16:33:48 UTC
From: WD8ARZ
Topic: 31451 Message: 31455

Glad we have moderators that maintain a goal for the purpose of a forum. Other forums can be set up for other topics.

Me, I even take it a step further or two ....

All subject header messages are deleted with out being read or added to the archive maintained here. When searching for topics of interests, subjects are required.

Threads that have been hijacked into topics that dont represent the topic anymore, are treated the same way.

Persistent offenders are put into an email deleting / blacklist / bouncing program for that user, so no further messages are received by that user ....

A separate program is ran that looks at all email messages on the server 'before' downloading into my mail program. That keeps my mail program free of problem emails and abusers.

Note: All emails to me personally on this subject will have my reply to include this group forum.

Here in dl I know a VERY good company

http://www.frick-geraetebau.de/

from smaller telescopic poles to really big towers

round shape (telescopic push up pole)

or SQUARE ... with built-in winch for pushing out and retracting

biggest one is about 90 feet

so a 30 to 40 feet is an easy thing for that company

dg9bfc

sigi

ps ... not a cheap thing ... but maybe you can borrow some ideas from the pictures

From: siegfried jackstien
Topic: 31147 Message: 31457

You should check ALL connections in the stacked antenna design

ALL (and I REALLY MEAN ALL) manufacturers make nice stacked antennas where the parts are just crimped together (and some are wiggling even when brandnew!!)

Solder them together

Maybe adding a small wire bridge (also soldered) across the connection point

Just make the design a bit more "sturdy"

I looked in comet, diamond and many "no-name" antennas (clones of the original) ... and ALL SHOW THE SAM THING

When brand new and all contacts are shiny then the antenna works superb ... but after a while when the wiggling contact areas are corroded ...then sometimes the antenna works and sometimes not (swr is jumping all over the place on a windy day)

And as I already wrote ... that is in ALL antennas that are built that way (stacked dual or tribander) regardless if it is a clone or an original

Dg9bfc

I received several replies regarding my previous post about having problems with my G5RV and reflected power. I found several things wrong, first I had to clear the memory from my antenna tuner, according to the manual this should be done if tuning issues occur. Second my matching section had gotten wind blown behind the mast and was lying against aluminum siding. After doing these two things and going back through the antenna tuner set up my system looked much better. Around 80watts output with no measurable reflected power. From the mtn of western NC I talked with an ARRL station in western mich., and talked on a 40M net from the gulf coast of fla. into the DC area with a SWR of around 2:1. I am sure there is more to be done but thanks to your input I am moving in the right direction.

Don't hold your breath for CB or FRS. I have heard this CW "discussion" since the 60s, one group saying that if we dropped the code it will turn Amateurs into brain-dead zombies or that CW was one step from the second coming. The bands are big enough for the CW people to operate, I am just not one of them. The last time I used CW was to get my Tech Plus..

Because there is nothing in the rules of this group to stop it.
Did you not get the rules when you joined?

Here they are.

" OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is
prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS
will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over
onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the
transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the
Moderators, because public postings may likely result in penalties as above.
!!!!
12. Use common sense. If you would be hurt or upset if you received what
you are about to send, and you are intentionally meaning to do that,
DON'T DO
IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more. "

Per number 13 doesn't stop other discussion unless you violate the other 12 rules.

Jerry, have you looked at Wil-Burt?

I have a 24 footer they make that's about 6 foot folded down, and it goes up manually and spec'd to carry a little over a 20 pound load.

They are expensive, but turn up used, mine came from a broadcast station that used it for remotes.

Nice stuff if you can find it.

Good luck, like ur project,

73 Scott

Topic: 31465 Message: 31465

Does anyone have an EZNEC example file for a fan dipole they can share? I want to play around with different wire lengths, but don’t know how to add the second set of wires to the source.

A good word of caution to pass along Sigi. I will add to this and say the same is true for manufactured wire antennas. The fine print on double bazookas and "Mystery Antennas" state to hang them in an inverted vee configuration. The reason is that close inspection and common sense will tell you that they will break otherwise. No way, I have the room, I want horizontal, and there is a fix that works very well for me until I cycle them out and have 100% home made. Although from different respected companies, they all had sealed tubular center insulators with an external SO-239.

Step 1. Wrap with Press and Seal food wrap. It is thick and holds well. This also keeps the insulator clean if you have to remove the coverings later.

Step 2. Run a length of black Dacron rope across the insulator and about three inches of the antenna legs. Wrap the rope, insulator, and three inches of rope on the antenna legs with 20-30 lb test braided Spiderwire fishing line. It is very thin, and this will take a bit of time but time well spent.

Step 3. Add coax seal and a layer of quality tape. If you do not live in an HOA neighborhood, add a layer of PINK liquid tape to help with those after storm midnight inspections. Using the quarter inch rope, you have just upgraded the center insulator internal connections to a 900 lb break strength. If the tree does not fall or the pulleys break, the antenna is there until you want it down.

Hi Scott:
Hopefully you can get an answer on your question. I sincerely hope you do not mind me adding a few more questions to yours, as I am going to do one as well soon.

I suck at EZNEC, but could you define your version a bit more? In the past I have done a plus sign single feed where all four elements are at 90 degree angles. I have been told that qualifies as a fan, although I just considered it a multi-leg dipole. I see a fan dipole as one with multiple legs run parallel and a single feed. I'll throw up some points on what I know and what I do not know. Maybe we will get further comment. I say that because I have a pile of PVC, a lot of wire, and a lot of rope and pulleys to use. I am looking at a three or four band flavor.
From what I have read, a quality 1:1 balun for the center connections is essential. Never buy those $30 baluns. I am still ticked from 3 years ago and learned my lesson. The trouble that thing caused when it fried far outweighed the extra $40 including shipping to get quality. Balun Designs is one of the good sources and they answer the phone. DX Engineering and others also good. If the elements are parallel, the antenna will become heavy and will need center support. In addition, if using a quality balun as the center insulator, it will have a bottom drain hole and will need to stay properly oriented up and down to drain properly.

I have read to always build one band at a time starting with the lowest band working your way to the highest band and leave some twist back slack and do not solder the ends until all bands are completed, as you may have to back track.
I have read in a parallel configuration, spacing elements through the PVC is important, although I have found no consensus on a sweet spot. I could make it almost anything needed for a sweet spot and paint it pink as there is no HOA to deal with.
I have read using insulated antenna wire is desirable to avoid any effect of water interaction that could occur at the pass-thru holes in the PVC. I have a couple hundred feet I bought from Wireman a while back. Using insulated antenna wire does affect the generally accepted length for the elements.
A sacrificial rope to mount a pulley in the trees highly recommended as the antenna will be up and down a few times. I currently have two antennas up with the ropes grown into the trees. When they die it will suck to be me.

I have also read good SWR bandwidth will narrow as more band legs are added to a fan dipole.

Antenna Analyzer.....the right one makes the job easier and worth the investment. Rig Expert makes a few dandies. The AA-54 and higher number models can take a single feed antenna and with simple software, an input of up to five frequency ranges, i.e. fan dipole, and in seconds give you the SWR for all five freq ranges and more. The 54 model and higher has internal storage and interfaces to MAC, Windows, and Linux on a PC or laptop. I do not work for them, but I love the product.

It can get tense if you add the 3rd harmonic antenna by mistake or intention. Also some say the various dipoles should be well spaced apart from one another. What "well spaced" means, I'm not too sure anymore.

I guess that is one advantage the GP-15 has, it's a single piece vertical element with three horizontal elements that screw into the base.

Great advice PCHAPMAN, but i am trying to get my head around your description, pics would be very helpful, (yah i am not suggesting you take your Antenna down , lol), but how do you attach the Rope with the Spider Fish line together when wrapped ? IS the Dacron Rope at leg ends also wound or just run length wise then wound /wrapped with spider fishline ? Thanks because i am just about to put up my First OFC ,(off center fed), wire Antenna in over 40yrs ! lol Just got my Ticket again , and having fun setting up the Shack, all used stuff but it will be good enough . 73s AJ KF5ZYB in the OZARKS

I built a 3 band fan several years ago for 40 , 20 and 10 metres . start with the lowest band you want to use , adjust it for centre frequency of your band and add the next higher band wire , adjust it the same way and then add the next one .

I did not model it , just adjusted the length one at a time until I got the swr to 1.3 on all 3 bands . never tried adding a 4th band .

Hi Paul,

My goal is to hang a two band (160 and 80) fan dipole off my tower. I am not sure if the wires should be in parallel and how much this will change the bandwidth. Since I own EZNEC, it would be nice to model the antenna before I start the process of trimming it. My plan is to purchase a Balun Designs Model 1113e and hang the 160 dipole first. When I get the 160 trimmed, I will add the 80 wire and see how it plays. Please note that I have EZNEC+ 5.0.62.

Subject: [ham-antennas] RE: EZNEC Fan Dipole Model

Hi Scott:
Hopefully you can get an answer on your question. I sincerely hope you do not mind me adding a few more questions to yours, as I am going to do one as well soon.

I suck at EZNEC, but could you define your version a bit more? In the past I have done a plus sign single feed where all four elements are at 90 degree angles. I have been told that qualifies as a fan, although I just considered it a multi-leg dipole. I see a fan dipole as one with multiple legs run parallel and a single feed. I'll throw up some points on what I know and what I do not know. Maybe we will get further comment. I say that because I have a pile of PVC, a lot of wire, and a lot of rope and pulleys to use. I am looking at a three or four band flavor.
From what I have read, a quality 1:1 balun for the center connections is essential. Never buy those $30 baluns. I am still ticked from 3 years ago and learned my lesson. The trouble that thing caused when it fried far outweighed the extra $40 including shipping to get quality. Balun Designs is one of the good sources and they answer the phone. DX Engineering and others also good. If the elements are parallel, the antenna will become heavy and will need center support. In addition, if using a quality balun as the center insulator, it will have a bottom drain hole and will need to stay properly oriented up and down to drain properly.

I have read to always build one band at a time starting with the lowest band working your way to the highest band and leave some twist back slack and do not solder the ends until all bands are completed, as you may have to back track.
I have read in a parallel configuration, spacing elements through the PVC is important, although I have found no consensus on a sweet spot. I could make it almost anything needed for a sweet spot and paint it pink as there is no HOA to deal with.
I have read using insulated antenna wire is desirable to avoid any effect of water interaction that could occur at the pass-thru holes in the PVC. I have a couple hundred feet I bought from Wireman a while back. Using insulated antenna wire does affect the

generally accepted length for the elements.
A sacrificial rope to mount a pulley in the trees highly recommended as the antenna will be up and down a few times. I currently have two antennas up with the ropes grown into the trees. When they die it will suck to be me.

I have also read good SWR bandwidth will narrow as more band legs are added to a fan dipole.

Antenna Analyzer.....the right one makes the job easier and worth the investment. Rig Expert makes a few dandies. The AA-54 and higher number models can take a single feed antenna and with simple software, an input of up to five frequency ranges, i.e. fan dipole, and in seconds give you the SWR for all five freq ranges and more. The 54 model and higher has internal storage and interfaces to MAC, Windows, and Linux on a PC or laptop. I do not work for them, but I love the product.

I made a fan dipole for my QTH here. I just used basic math the calculate the lengths of each band. I made it for 40, 20, 17, 12 meters. I added at the last minute 15 meters.
I used 3/4 inch PVC to space them out approx 3 1/2 inches apart. I'm my research and reading about fan dipoles I can to the conclusion that yes the will react with each leg that will end up being shorter than the calculated length.
I have a little bit high swr on 40 but I am still about to tune it with an auto tuner.
I'm no expert on antennas but from my 5 band fan dipole I have had no problems with each leg reacting with each other.

Hope this helps...

Scott:

I don't know how much room you have, but back in the 1970s, I would make a particular type of antenna for those I was helping to "Elmer". This antenna, although quite simple, cheap, and easy to install, always seemed to work quite satisfactorily for those who used it.

It required two coaxs.

First, I would install a 16' tall vertical, fed at the bottom with RG-8, and made out of steel TV mast on the top of the ham's house. This was for 20 and 10 meters. (There were no WARC bands at the time.) I would also run 4 "radials" which acted as a ground-plane for the vertical. The radials sloped down the roof.

Then, from the top of the vertical, I would hang two inverted-vees, one cut for 40 (which also worked on 15) and one for 80. They would be fed with a single piece of RG-8.

These would be set at right-angles to one another.

The inverted Vees would also act as guys for the vertical.

Since the vertical support was on top of the roof of the house, that got the Vees to a height of at least 30 feet.

Every one who used one of these found it quite satisfactory, and the SWR was always reasonable.

Perhaps in your case you could set your dipoles at right angles to one another and this would reduce any interaction.

Others here would have far more knowledge of such than I, and I would be very interested to see what EZNEC or something better would show for it.

Since the radiation pattern for an inverted Vee is very close to omni-directional, "crossing" the Vees appeared to make no changes in that pattern. Of course, at the time, we had no accurate method of measuring that.

I did a quick run on EZNEC and while I don't have actual information on the height of the tower and how high you can make the end points, or the section of the bands of interest, but Ken is correct and the antenna as he describes can be tuned to any section of either band without much interaction, and match <1.2-1.5:1. If you would like to share more information, I will run it and send you the EZNEC file. I ran it on EZNEC 5 also. Cheers,

Mel, K6KBE

There are other companies that have a similar V-dipole.

Just wondering if a 44 ft V-dipole (22 ft elements), that is ladderline fed wouldn't be a better antenna? Certainly less cost. It covers 20 thru 10 meters very well. This antenna was one of Cebik's (W4RNL...sk) great ideas!

Hello again Scott:
I took a look at the place from satellite view. It appears as though the tower is situated pretty much center of the lot behind the house with a thick stand of hardwood trees as you go further away from the rear of the house. Looks like the lot is more deep than wide and you have houses on either side. There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. To go with a non parallel configuration single feed, I think someone on this forum, or it could have been my club forum, mentioned to not have arcs of each element pair less than 45 degrees and try to go 60 degrees if at all possible. This would bring up a mounting situation for the balun to maximize the angles, as you may have to get the balun, also being used as a center insulator, away from the tower 2-4 feet. I would not know if hanging it from some galvanized strapping bolted horizontal across the tower (so the strapping would have two bolting points) would create interaction issues, or whether some heavy duty PVC would be better to prevent that. In either case, you would most likely need to go with a three eyebolt balun which is the same price. It is obvious considering your band choices why you thought parallel fan. Stacked parallel individual feeds would be a problem. Adjacent does not work considering the band choices, as again, not enough separation room side to side. In addition, the fan configuration would leave one entire side of your property to do something else on the higher bands. As a final thought, digest the information from all of the good suggestions the great group of hams here have thrown out, go to Google search, plug in your address, zoom to cover your lot and a bit of your neighbors as well so that the property lines are evident, hit screen print key on your keyboard, then open MS Word or Paint and right click paste or control V, (you may have to resize the image to make it fit) attach it to an email to bob@balundesigns.com mailto:bob@balundesigns.com (If you need help on the computer side, contact me off list, and I will put it together for you or send it to Bob on your behalf.) Be sure to be brief yet cover your needs, in particular balun mounting to prevent interaction. In a fan configuration, this will be a heavy antenna due to length/drop angle/resultant stress. Bob may have a mod in mind he could do other that the standard eyebolt which would be a worthy additional investment. I wish you luck and let us know how this works out in the final result.

Hi Doug,
I have one of their roof towers that is eons old and had to contact them for some information and support regarding the tower close to 30 years after its manufacture. Language can be a slight issue, but nearly everyone in Japan industry speaks English, so you request will get routed to an appropriate party. The still support the tower and everything I requested was provided. Speaking from the support I received, and the quality of the tower (far better quality than my much newer Glen-Martin), I can only say very good things about the firm.
As for their rotatable dipole I have no experience (mine is a Cushcraft D-40 for 40 meters), but if the workmanship and quality is anywhere near what I have found with their tower, it will be an excellent product. I talk to a friend in Japan with one of Create's five band dipoles and he swears by it because it comes with and uses a band matching transformer (tuner) that allows him to tune right into where he wants to be.

Thanks for posting this. Sure, it's an advertisement for BuddiePole, but that's okay. I've been considering buying a BP or BuddieStick, but I've never seen either in actual use. Very impressive! Of course the salt water didn't hurt, either.

Thanks Randy. I'll try calling again and maybe this time I'll get someone with better English.

Thanks

31502. File - rules2.txt

Yahoo group: ham-antennas (2014)
Date: 2014-03-01 22:41:36 UTC
From: ham-antennas@yahoogroups.com
Topic: 12267 Message: 31502

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

31506. Rotor for Pneumatic Mast

Yahoo group: ham-antennas (2014)
Date: 2014-03-02 05:23:26 UTC
From: <jsternmd@...>
Topic: 31506 Message: 31506

I have never worked with mast/tower antenna having survived with long wires till now. I live in a semi-CCR community and my original plan was to go with a lightweight Hexbeam and lightweight rotor but I am wonder if I could manage a Yagi. I could get away with a small footprint yagii for 20-15-12-10 if I could keep the profile off my roof and somewhat inconspicuous except when in use. I came upon a relative bargain for a new 30' foot pneumatic mast. It weighs about 100 lbs and has a 4.5" diameter at the lowest section with a top section load capacity of about 65 lbs. My plan is to mount the pneumatic mast onto a 6"x6" post anchored into concrete and controlled remotely. I would like to keep all of the load capacity for the antenna and so I am wondering if it is realistic to consider a heavy duty rotor inverted at the base of the mast. Could a typical heavy duty rotor with a 2" mast mount be effectively converted to accommodate a special adapter for the 4.5" base? Also where could I get large enough custom 4.5" thrust bearing? Is this too far -fetched and should I just be happy with a hexbeam?

Hi Jerry,

If you Google the USTower MARB 40 rotating base fixture, you'll see something that is probably well suited to your needs, although not cheap.

I've used one to hold, rotate and tilt over a slightly shorter Wil-Burt mast for my hex with it just mounted to a pair of landscaping timbers in the shape of an x laying on the ground with no concrete, although bolted to concrete it's a simple and elegant solution.

In any event you could probably order a thrust bearing replacement from them or find out where they source it. A medium size rotor like a CD 45 easily turns a 40 steel tower in that base, and the top of the thrust bearing has an upwardly directed u bracket that accepts the base and is easily used for mast probably 6 inches and smaller. I can send ya a few pics if it helps.

It sounds like a really nice installation you're planning, the 6 by 6 post is probably the weak link compared to a steel one like the MARB, and if you could find a used one, would support your mast and all the weight it would carry easily and keep the rotor at the base.

HI Dave, it's nothing special really, see attached, but has worked really well. The Wil-Burt's out of it now as I'm building a bracket to fit ithe Wil-burt to my Jeep for summer, 3 inch homebrew aluminum 30 footer in there instead, no guys at all except at 4 ft on the base.

I haven't posted to Yahoo groups that I recall, is it easy?

31513. Antenna efficiency: Comparing the Alpha Loop & Alex Loop

Yahoo group: ham-antennas (2014)
Date: 2014-03-02 22:34:49 UTC
From: <aa2nh@...>
Topic: 31513 Message: 31513

Antenna efficiency: Comparing the Alpha Loop & Alex Loop
I have spent much time inputting all of the variables into
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for the bands that are safe to operate both the Alex and Alpha Loop on, and found why the Alpha Loop has more gain.
The measurements from Alex for his loop are Length of Conductor (antenna "circumference") = 10.3 feet & Diameter of Conductor .32 inches.
Here are the calculated efficencies for the Alex and Alpha Loop antenna's. Please not that the Alpha Loop's measurements are Length of Conductor = 9.92 feet & Diameter of Conductor = .477

Antenna efficiency - The Alpha Loop VS the Alex Loop
From 7 to 7.3 MHz
Alpha Loop; 8% - 9%
Alex Loop; 6% - 7%

From 10.1 to 10.150 MHz
Alpha Loop: 23% - 23%
Alex Loop: 18% - 18%

From 14 to 14.350 MHz
Alpha Loop: 48% - 50%
Alex Loop: 41% - 43%

From 18.068 to 18.168 MHz
Alpha Loop: 69% - 70%
Alex Loop: 63% - 63%

From 21 to 21.450 MHz
Alpha Loop: 79% - 80%
Alex Loop: 74% - 76%

An alarming find when I input Alex's measurements for his loop into
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.66pacific.com/calculators/small_tx_loop_calc.aspx for 10 through 12 Meters occurred. On those frequencies a RED message appears that says:
"To avoid self-resonance, the conductor length for a small transmitting loop antenna should be less than 1/4 wavelength."
I now understand why the AlexLoop should not be used on 10 & 12 Meters, which is because exponential increases in resistance will occur on a small transmitting loop when self-resonance occurs, which can damage equipment.
For more information on this, see the section titled "Inductance and self-resonance" here:
http://www.antennex.com/preview/Dec03/Dec603/Loopantennas.htm
http://www.antennex.com/preview/Dec03/Dec603/Loopantennas.htm

31514. Re: [ham-antennas] RE: EZNEC Fan Dipole Model

Yahoo group: ham-antennas (2014)
Date: 2014-03-02 22:58:42 UTC
From: Scott Souva
Topic: 31465 Message: 31514

Hi Paul,

Great minds must think alike. I contacted Bob via email and he recommended an alternative configuration to support the balun and strain on the eye-bolts. His recommendation was the Model 1116d (better for lower frequencies) mounted to the DLP5 Dipole Plate. I will likely purchase the 1116dt (studs on top) with the DLP5 for my configuration.

Thanks for the good ideas on hanging the antenna from the tower. Now I need the weather to improve (stop snowing...) for this next project to begin.

73 de KG2S,

Scott

From: p_chap@...

Subject: Re: [ham-antennas] RE: EZNEC Fan Dipole Model

Hello again Scott:
I took a look at the place from satellite view. It appears as though the tower is situated pretty much center of the lot behind the house with a thick stand of hardwood trees as you go further away from the rear of the house. Looks like the lot is more deep than wide and you have houses on either side. There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. To go with a non parallel configuration single feed, I think someone on this forum, or it could have been my club forum, mentioned to not have arcs of each element pair less than 45 degrees and try to go 60 degrees if at all possible. This would bring up a mounting situation for the balun to maximize the angles, as you may have to get the balun, also being used as a center insulator, away from the tower 2-4 feet. I would not know if hanging it from some galvanized strapping bolted horizontal across the tower (so the strapping would have two bolting points) would create interaction issues, or whether some heavy duty PVC would be better to prevent that. In either case, you would most likely need to go with a three eyebolt balun which is the same price. It is obvious considering your band choices why you thought parallel fan. Stacked parallel individual feeds would be a problem. Adjacent does not work considering the band choices, as again, not enough separation room side to side. In addition, the fan configuration would leave one entire side of your property to do something else on the higher bands. As a final thought, digest the information from all of the good suggestions the great group of hams here have thrown out, go to Google search, plug in your address, zoom to cover your lot and a bit of your neighbors as well so that the property lines are evident, hit screen print key on your keyboard, then open MS Word or Paint and right click paste or control V, (you may have to resize the image to make it fit) attach it to an email to bob@... (If you need help on the computer side, contact me off

list, and I will put it together for you or send it to Bob on your behalf.) Be sure to be brief yet cover your needs, in particular balun mounting to prevent interaction. In a fan configuration, this will be a heavy antenna due to length/drop angle/resultant stress. Bob may have a mod in mind he could do other that the standard eyebolt which would be a worthy additional investment. I wish you luck and let us know how this works out in the final result.

31515. Forced into a bad antenna situation

Yahoo group: ham-antennas (2014)

From: ko1h
Topic: 31515 Message: 31515

Hi all , I am being forced into a bad antenna situation by having to move. I'm not moving far but im loosing most of my elevation. Also I will have a small hill rising about 50ft directly behind the yard to my NW. I assume this will do in most of my ability to work JA/BA etc.

That aside in trying to conjure up what will be an effective little antenna system to make the most of what I will be left with.

First a few caveats. NO TOWERS, NO Masts etc.

Landlord seems to be ok with a wire in the tree's and a vertical out of the way.

First thoughts are as much doublet as I can wrangle in the tree's fed with open wire directly to my tuner.

Second would be some kind of vertical (Likely a 6btv with radials in the weeds.) As time goes on I may try to camo paint and had my 30m Sigma and perhaps one of those Force 12 10-20m verticals that can be used as a plant stand.

Well any suggestions for the soon to be terrain limited. Appreciated. It sucks having to come down from the mountain but better than being on the street 8)

I live in an antenna restricted neighborhood, but have put up a 15 ft mast with a Comet CHA250BX on top. It blends into the background of trees very well since I camouflage painted it. I looks like a stick. It does well, but I would like something similar, but with the ability to handle more than 250 watts.
The closest antenna I have found is the Cushcraft R9, but it has stuff hanging off it a several intervals, is taller and weighs over 25 pounds vs 7.1 pounds for the Comet.
Any good ideas?

Scott,

My apology I have not responded until now. I've had several versions of fan dipoles (all hombrew) and the last one I built has been on my tower for going on 3 seasons. I have posted photos of its construction here. I got this basic design from another ham on the internet through a Google search some years ago and modified it to make it work for me. The photos are before anything else was on the tower.

https://groups.yahoo.com/neo/groups/ham-antennas/photos/albums/309889546

This dipole has wires for 80/40/20/10 and is resonant on 15 on the harmonics of the 40M wire. Each wire is about 6" from each other at the feed point and is wrapped a couple times around the 6 gauge solid and then twisted back on itself and then all soldered (via propane torch) to that 6 gauge solid behind the 3/4" PVC and pipe conduit and fittings. Once it was all soldered, it was sealed and then pushed into the PVC conduit. The wires pass through the PVC conduit as holes are drilled through it, so it is the PVC conduit that holds the wire tension. By separating the feed points, it makes tune up much easier with less interaction. I used a 1115 unun because I already have several of that design. Certainly using one with studs would be easier to wire into the feed point, as I have to make a little custom coax jumper and seal it up on mine. The wires are spaced by around a foot out at the ends. It covers all of 40/20/15/10M below 2:1 and on 80M, is below 2.5:1 through the entire band. (I attribute the wide bandedness on 80M to the capacitive loading of the other wires.) The lower piece of PVC that sticks out the bottom was for use on a field day (for which it was originally built) and I don't use that any longer and it isn't anything you need if you are only going to hang it... although I found that PVC stub came in handy to secure the coax to to keep the feed point from moving due to wind. I really hadn't intended on making this a more permanent part of my antenna system, but I liked the way it performed, so I did.

Sorry, I have never modeled it and I am pretty good with EZ-NEC. Dealing with the feed points in EZ-NEC would be a challenge. I really should model it to see what it looks like in theory.

Hi Paul,

Great minds must think alike. I contacted Bob via email and he recommended an alternative configuration to support the balun and strain on the eye-bolts. His recommendation was the

Model 1116d (better for lower frequencies) mounted to the DLP5 Dipole Plate. I will likely purchase the 1116dt (studs on top) with the DLP5 for my configuration.

Thanks for the good ideas on hanging the antenna from the tower. Now I need the weather to improve (stop snowing...) for this next project to begin.

Hello again Scott:
I took a look at the place from satellite view. It appears as though the tower is situated pretty much center of the lot behind the house with a thick stand of hardwood trees as you go further away from the rear of the house. Looks like the lot is more deep than wide and you have houses on either side. There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. To go with a non parallel configuration single feed, I think someone on this forum, or it could have been my club forum, mentioned to not have arcs of each element pair less than 45 degrees and try to go 60 degrees if at all possible. This would bring up a mounting situation for the balun to maximize the angles, as you may have to get the balun, also being used as a center insulator, away from the tower 2-4 feet. John
The 300 ohm line has slightly more loss (depends on the construction and manufacturer to some degree) than 450 ohm . Old fashioned solid dielectric TV Twin Lead has more loss than the window variety of 300 ohm. At HF you are unlikely to notice the difference

Assuming your using an antenna tuner to match this to your 50 ohm transceiver. expect the tuning to change every time the line gets wet (which happens a LOT in Tallahassee) . Water collects on the surface of so the called commercial window lines and changes the dielectric constant slightly which in turm changes the charactersitic impedance of the line slightly. True homemade LADDER line with dowel style spacers is much less subject to this affect. If your going to use a balun expect the same problem between dry line and wet line

Wish I knew where it was, but I've read of tests done suggesting that the value of ladder line was in some circumstances important as to how easy it was to match the antenna in a multi-band setup. It kept the impedance at the tuner's end to more reasonable values... made it easier on the tuner, keeping internal losses to a more manageable amount.
IIRC, the results tended to lean towards the 450 ohm stuff.

I doubt that you will see much difference in "loss", but the comment about ease of matching really depends on the limits of the impedances you are likely to see on your antenna. I find that really high impedances are better served with 450 or 600 ohm line preferably the dogbone type. On OCF dipoles the match works well with 300 ohm or higher lines. You know the input vs the output transformation ratios and all that.

Dale,

I honestly don't have the lengths. I started with standard theoretical lengths plus and extra couple of feet. HOWEVER, if you are in no hurry, I can get them for you. The whole things goes up and down an a pulley very easily. A friend of mine wants to tune a trap dipole in a couple of weeks and wants to use my tower to do it. So if you can wait, I'll take some exact measurements of everything when I bring it down and post then. If you haven't heard from me in a month, shoot me a reminder via a private e-mail.

There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. To go with a non parallel configuration single feed, I think someone on this forum, or it could have been my club forum, mentioned to not have arcs of each element pair less than 45 degrees and try to go 60 degrees if at all possible. This would bring up a mounting situation for the balun to maximize the angles, as you may have to get the balun, also being used as a center insulator, away from the tower 2-4 feet. I would not know if hanging it from some galvanized strapping bolted horizontal across the tower (so the strapping would have two bolting points) would create interaction issues, or whether some heavy duty PVC would be better to prevent that. In either case, you would most likely need to go with a three eyebolt balun which is the same price. It is obvious considering your band choices why you thought parallel fan. Stacked parallel individual feeds would be a problem. Adjacent does not work considering the band choices, as again, not enough separation room side to side. In addition, the fan configuration would leave one entire side of your property to do something else on the higher bands. As a final thought, digest the information from all of the good suggestions the great group of hams here have thrown out, go to Google search, plug in your address, zoom to cover your lot and a bit of your neighbors as well so that the property lines are evident, hit screen print key on your keyboard, then open MS Word or Paint and right click paste or control V, (you may have to resize the image to make it fit) attach it to an email to <mailto:bob@balundesigns.com> bob@... (If you need help on the computer side, contact me off list, and I will put it together for you or send it to Bob on your behalf.) Be sure to be brief yet cover your needs, in particular balun mounting to prevent interaction. In a fan configuration, this will be a heavy antenna due to length/drop angle/resultant stress. Bob may have a mod in mind he could do other that the standard eyebolt which would be a worthy additional investment. I wish you luck and let us know how this works out in the final result.

I have used a MFJ-1796 Vertical Dipole with good results for 20 years. It does not require radials because a dipole is a balanced antenna. The bandwidth is rather narrow on 40 and 20 because of the small size, only 12 feet vertical and 2 feet in diameter. You can cover the entire band when using a tuner. 1500 Watts PEP max on all bands lower than 6 meters. 750 Watts on 6 and 300 Watts on 2 meters. Low takeoff angle makes it good for DX but inferior to a horizontal antenna at distances less than 600 miles.

Scott
that sounds good. I can wait as there is to much snow and to cold for me to work on antennas outside right now.

Dale,

I honestly don't have the lengths. I started with standard theoretical lengths plus and extra couple of feet. HOWEVER, if you are in no hurry, I can get them for you. The whole things goes up and down an a pulley very easily. A friend of mine wants to tune a trap dipole in a couple of weeks and wants to use my tower to do it. So if you can wait, I'll take some exact measurements of everything when I bring it down and post then. If you haven't heard from me in a month, shoot me a reminder via a private e-mail.

like the looks of your antenna. looks like something that might work for ma as a way to get on 80-10.

was wondering if you have the length of the wires you used and could send them to me.

Scott,

My apology I have not responded until now. I've had several versions of fan dipoles (all hombrew) and the last one I built has been on my tower for going on 3 seasons. I have posted photos of its construction here. I got this basic design from another ham on the internet through a Google search some years ago and modified it to make it work for me. The photos are before anything else was on the tower.

https://groups.yahoo.com/neo/groups/ham-antennas/photos/albums/309889546

This dipole has wires for 80/40/20/10 and is resonant on 15 on the harmonics of the 40M wire. Each wire is about 6" from each other at the feed point and is wrapped a couple times around the 6 gauge solid and then twisted back on itself and then all soldered (via propane torch) to that 6 gauge solid behind the 3/4" PVC and pipe conduit and fittings. Once it was all soldered, it was sealed and then pushed into the PVC conduit. The wires pass through the PVC conduit as holes are drilled through it, so it is the PVC conduit that holds the wire tension. By separating the feed points, it makes tune up much easier with less interaction. I used a 1115 unun because I already have several of that design. Certainly using one with studs would be easier to wire into the feed point, as I have to make a little custom coax jumper and seal it up on mine. The wires are spaced by around a foot out at the ends. It covers all of 40/20/15/10M below 2:1 and on 80M, is below 2.5:1 through the entire band. (I attribute the wide bandedness on 80M to the capacitive loading of the other wires.) The lower piece of PVC that sticks out the bottom was for use on a field day (for which it was originally built) and I don't use that any longer and it isn't anything you need if you are only going to hang it... although I found that PVC stub came in handy to secure the coax to to keep the feed point from moving due to wind. I really hadn't intended on making this a more permanent part of my antenna system, but I liked the way it performed, so I did.

Sorry, I have never modeled it and I am pretty good with EZ-NEC. Dealing with the feed points in EZ-NEC would be a challenge. I really should model it to see what it looks like in theory.

Hi Paul,

Great minds must think alike. I contacted Bob via email and he recommended an alternative configuration to support the balun and strain on the eye-bolts. His recommendation was the Model 1116d (better for lower frequencies) mounted to the DLP5 Dipole Plate. I will likely purchase the 1116dt (studs on top) with the DLP5 for my configuration.

Thanks for the good ideas on hanging the antenna from the tower. Now I need the weather to improve (stop snowing...) for this next project to begin.

Hello again Scott:
I took a look at the place from satellite view. It appears as though the tower is situated pretty much center of the lot behind the house with a thick stand of hardwood trees as you go further away from the rear of the house. Looks like the lot is more deep than wide and you have houses on either side. There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. I forgot to mention what I used as spanner spacers. I used /2" PEX water tubing. Super cheap and very light weight. You cna find it in 10' straight sections if you look. You can buy it in a roll as well, but then you ahve to heat it with a heat gun and work it back to being straight, which is more time consuming, but can be done. Care has to be taken get the rope tension just right so as not to cause the spanners to want to bend. And for the record, the tension ropes are the most difficult part of putting a fan dipole together, if you want widely spaced wires; greater than 12" spaces at the ends.

I've used the 1796 and it does work fairly well.

But all the added gizmos hanging off the sides might be a problem due to the need to hide the antenna.

Hi John,
Sorry to hear you've got to "downsize" your antenna farm!

The Hustler BTV vertical series is very amenable to adding extra bands and modifications, as you probably already know. If the available yard or antenna supports is limited, might I suggest doing the "wire mods" for the 4 or 5 BTV, and then adding an inverted "L" portion to get higher efficiency on 80 and 160m bands? No reason the traps couldn't be homebrew from coax instead of commercial; would lead to shorter "L", especially for 160m.

The Hustler Vertical series, by Newtronics, has got to be the best value on the ham antenna market today. They are well built and suffer few mechanical problems; parts are readily available from the manufacturer or through their distributors. Current price from DXEngineering on a Hustler 5BTV is $160 or $125 on a 4BTV.

Most mods are available here, at Hamuniverse, keyword is "Hustler":

For classic verticals, it is hard to beat a Butternut HF6V, Above the 5' mark, it is very wispy indeed (much smaller OD than a BTV) and can handle not being guyed. It is also without the loss of the traps of a Hustler. It is more expensive than the Hustlers however. But because it is so light weight with all its weight at the bottom, it can be taken up and down very easily with the removal of one small screw. And of course painting it is also an option to assist in the stealth. I used one for 10 years on a deed restricted property.

Beyond that, the SteppIR verticals are probably the most easy to hide and maximizes efficiency, as it has no loading coils, traps or any other such appendage; just the small box at the base. But they come at a much higher price point unfortunately.

OK, Gang, I'm going to share some info with you, then will ask for some advice. If I cram everything I want to say into this e-mail, its going to be pretty long. If it is too long for you, just delete it.

First the info: As I have mentioned here at least once before, my only antenna is a 55' tall 2-band (80/40) trap-vertical with the trap/loading coil at the 33' level. I have only 4 ea 66' long radials lying on the ground at the moment, but plan to add more this summer. With my home-brew antenna coupler, I can match any band I want to operate on to 50 ohms with very close to 1:1 SWR. I use a base-loading coil on 160 and it works fine.

About 2 months ago or so, all of my "modern" rigs (TS-940SAT, TS-820S, and others) crapped out all at once. While I am waiting to get one or the other off the bench and back in operation, I have been using a Heathkit HW-16 with the 15 meter band modified for 20 meters. I coupled that with a refurbished WRL-755A VFO, and use the combo to drive one of my SB-200s to full output on 80, 40, and 20. It's great fun, and useful to meet my traffic handling skeds, but is pretty limited and not particularly handy.

The other day, a Yaesu FT-890 which has been loaned to me by a friend arrived, and I hooked it up.

I was absolutely amazed and appalled to see what my ambient, constant noise level is. I knew it was pretty bad, but this is ridiculous. It sits at S-9+ on 160, 80, 60, 40, 30, and 20 practically all day. It is less on the higher bands, but not much. This morning on 20 it dropped back to about S-8 for an hour or two, but then went right back up as the band fully opened up.

The Noise Blanker in the FT-890 does absolutely nothing to mitigate this either. I have obviously had this noise level for a long time, but never really noticed how bad it was before I got this rig in operation.

At this point, I am convinced that the main source of noise is simply the fact that my antenna is a vertical, and a big one at that. I know verticals tend to be more noisy than other antennas, but this is ricidulous.

I have gotten out my ARRL Antenna Book (an older one) and have been looking at other antennas that I might be able to install here, but so far, have not been happy with what I have found.

Our lot, in the middle of Moscow, Idaho, is approximately 50 feet wide (N-S) and a little over 120 feet long (E-W). Neighbors are tight up against the property lines on both sides. Our home sits very near the west edge of our property, (If the house were in the center of the property, it would make installing an inverted vee, for instance, somewhat easier). To the east rises a hill which continually steepens until at its top it is at least 100 feet higher than our property. Down the alley to the east of us runs a 13.6 KV power line,

which, by the way and surprisingly, does NOT seem to be the source of much of the noise.

So, here is what I am reviewing:

1) an open-wire line-fed inverted Vee. Trouble is, the lot is too narrow to A) put one up very high and B) to spread the legs out to achieve an optimum angle.

2) A horizontal rectangular loop, mounted on poles above the fence that surrounds our property. Trouble is that, A) I will have some difficulty getting it very high (I can install poles alongside the 6 foot tall 4X4 posts which are embedded in concrete), and B) both "long" sides will be right on the property lines and very near to neighbors who already experience interference to, and I get a lot from, their crappy non-shielded or filtered entertainment devices, and C) I cannot use the full 120' property length since to do so would put two of the poles right on the sidewalk.

3) A large vertical loop (30' diameter) built out of 3/4" diameter copper plumbing fittings and 3/4" copper pipe. Trouble is that, A) this must be rotated, and B) I have very few places I can mount it, and C) I suspect that since it is vertical, it wouldn't be any quieter than my vertical. This antenna is covered in detail in my ARRL Antenna Book. Has anyone here had any experience with such a loop?

4) An end-fed sloper with the far end in the 100'+ pine tree in the north-east corner of the yard. Trouble is, A) I wouldn't expect this to be any quieter than the vertical, and B) the high-far end would be within about 12 horizontal feet of, and about 6 vertical feet above, the 13.6 KV power line and therefore noise would probably be greater, and C) it would be right on the property line of our neighbor to the north.

5) A smaller, 3' diameter, stainless steel loop (made by Stoddart) mounted on or near the top of the roof on a rotator and used with a preamp ONLY for receiving. Trouble is, I think I would be unable to hear the stations who could hear me.

6) Install a high-performance noise phaser on the order of the one designed and built by Mike Murphy WU2D and published in this past month's ER Magazine. Trouble is, I'm not sure this will help with the type of noise I am experiencing.

Any suggestions from the "peanut gallery" will be most gratefully accepted.

Ken you have done your homework, hi. Most of this you know, but here is my 2 cents.

First off I would make a simple DF loop and see if you can identify the location of the noise source. I would be surprised if you have a single source, but at least if you do, it is addressable with noise cancelling devices.

Second, any antenna that is single ended that is not DC shorted is going to be noisy. That is, a dipole is more noisy than a folded dipole but you know this.

Third, any loop antenna even at low levels will be better than a non DC shorted antenna. Been there done that. I have had very good luck with a OCF dipole that is oriented to null a single source noise and it is multiband.

Fourth, and this is expensive, but at the end of the road is a remote HF system and operated off the internet. Lots of that going on and lots of support from those who have done it.

OK, some of this might be helpful. Good Luck,.

Mel, K6KBE

Hi Scott,

Your link with the photos is really useful and helps me envision how I want to hang my new antenna. I had not considered using PEX water tubing, but it sure looks like a good idea. Can I assume PEX weighs less than PVC? Also, what keeps the PEX tubing from moving on the wires?

I forgot to mention what I used as spanner spacers. I used /2" PEX water tubing. Super cheap and very light weight. You cna find it in 10' straight sections if you look. You can buy it in a roll as well, but then you ahve to heat it with a heat gun and work it back to being straight, which is more time consuming, but can be done. Care has to be taken get the rope tension just right so as not to cause the spanners to want to bend. And for the record, the tension ropes are the most difficult part of putting a fan dipole together, if you want widely spaced wires; greater than 12" spaces at the ends.

Subject: RE: [ham-antennas] RE: EZNEC Fan Dipole Model

Scott,

My apology I have not responded until now. I've had several versions of fan dipoles (all hombrew) and the last one I built has been on my tower for going on 3 seasons. I have posted photos of its construction here. I got this basic design from another ham on the internet through a Google search some years ago and modified it to make it work for me. The photos are before anything else was on the tower.

https://groups.yahoo.com/neo/groups/ham-antennas/photos/albums/309889546

This dipole has wires for 80/40/20/10 and is resonant on 15 on the harmonics of the 40M wire. Each wire is about 6" from each other at the feed point and is wrapped a couple times around the 6 gauge solid and then twisted back on itself and then all soldered (via propane torch) to that 6 gauge solid behind the 3/4" PVC and pipe conduit and fittings. Once it was all soldered, it was sealed and then pushed into the PVC conduit. The wires pass through the PVC conduit as holes are drilled through it, so it is the PVC conduit that holds the

wire tension. By separating the feed points, it makes tune up much easier with less interaction. I used a 1115 unun because I already have several of that design. Certainly using one with studs would be easier to wire into the feed point, as I have to make a little custom coax jumper and seal it up on mine. The wires are spaced by around a foot out at the ends. It covers all of 40/20/15/10M below 2:1 and on 80M, is below 2.5:1 through the entire band. (I attribute the wide bandedness on 80M to the capacitive loading of the other wires.) The lower piece of PVC that sticks out the bottom was for use on a field day (for which it was originally built) and I don't use that any longer and it isn't anything you need if you are only going to hang it... although I found that PVC stub came in handy to secure the coax to to keep the feed point from moving due to wind. I really hadn't intended on making this a more permanent part of my antenna system, but I liked the way it performed, so I did.

Sorry, I have never modeled it and I am pretty good with EZ-NEC. Dealing with the feed points in EZ-NEC would be a challenge. I really should model it to see what it looks like in theory.

Hi Paul,

Great minds must think alike. I contacted Bob via email and he recommended an alternative configuration to support the balun and strain on the eye-bolts. His recommendation was the Model 1116d (better for lower frequencies) mounted to the DLP5 Dipole Plate. I will likely purchase the 1116dt (studs on top) with the DLP5 for my configuration.

Thanks for the good ideas on hanging the antenna from the tower. Now I need the weather to improve (stop snowing...) for this next project to begin.

Subject: Re: [ham-antennas] RE: EZNEC Fan Dipole Model

Hello again Scott:
I took a look at the place from satellite view. It appears as though the tower is situated pretty much center of the lot behind the house with a thick stand of hardwood trees as you go further away from the rear of the house. Looks like the lot is more deep than wide and you have houses on either side. There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may

be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. To go with a non parallel configuration single feed, I think someone on this forum, or it could have been my club forum, mentioned to not have arcs of each element pair less than 45 degrees and try to go 60 degrees if at all possible. This would bring up a mounting situation for the balun to maximize the angles, as you may have to get the balun, also being used as a center insulator, away from the tower 2-4 feet. I would not know if hanging it from some galvanized strapping bolted horizontal across the tower (so the strapping would have two bolting points) would create interaction issues, or whether some heavy duty PVC would be better to prevent that. In either case, you would most likely need to go with a three eyebolt balun which is the same price. It is obvious considering your band choices why you thought parallel fan. Stacked parallel individual feeds would be a problem. Adjacent does not work considering the band choices, as again, not enough separation room side to side. In addition, the fan configuration would leave one entire side of your property to do something else on the higher bands. As a final thought, digest the information from all of the good suggestions the great group of hams here have thrown out, go to Google search, plug in your address, zoom to cover your lot and a bit of your neighbors as well so that the property lines are evident, hit screen print key on your keyboard, then open MS Word or Paint and right click paste or control V, (you may have to resize the image to make it fit) attach it to an email to bob@... (If you need help on the computer side, contact me off list, and I will put it together for you or send it to Bob on your behalf.) Be sure to be brief yet cover your needs, in particular balun mounting to prevent interaction. In a fan configuration, this will be a heavy antenna due to length/drop angle/resultant stress. Bob may have a mod in mind he could do other that the standard eyebolt which would be a worthy additional investment. I wish you luck and let us know how this works out in the final result.

Shortly answered a constant S8-S9 noise source on all bands is NOT the verticals fault. You most likely have a man made noise very near by.

The fact that several rigs died at once suggests a massive power line surge or lightning strike. This could have also caused a breakdown in a pole-pig transformer or lightning arrestor on the pole (i have experienced both as noise sources in the past) or any number of other appliances in your home that may be victim to whatever caused so many rigs to fail at once. In the dead of winter the quietest time of the year I would be very surprised to have noise peaks more than S1 or S2 on my (Bnut) vertical on 20M and 40M using a TS950SDX

I think it is best to use a length of 40, 80 ft.
Normally you buy enough ladder line and some extra.
Then cut it to a convenient length with a little extra.
Then trim or add as needed to get on all the bands you want .
I am assuming you are going to run the ladder line into an antenna tuner.

Indeed. What is that corollary about "unintended consequences"?

OK, Ron, I activated the FT-890's IPO control (Intercept Point Optimization) which, apparently, turns the RF amp off. (I assume this is actually the RF preamp you mentioned).

(According to the manual, the front panel "RF gain control" is, apparently ONLY an IF gain control, and has nothing whatever to do with the actual RF amplifier.)

This is still on 20 meters, where in the "quiet" part of the day, my noise level is still S-8+.

Activating the IPO, dropped the "S-meter" reading on noise from S-8+ to less than S-2, yet signal levels did not appear to drop. In fact, the noise level is hovering around S-1 or so now, and the audio doesn't sound nearly so noisy as before.

So, what does this actually mean? Does this really mean that my noise level isn't as bad as I thought, or does activating this control simply "mask" the noise and give me a false sense of security?

I am now wondering if the receiver gain was too high, and I was actually experiencing loads of intermod from all the signals and/or noise in the band.

I'm going to switch downwards in the bands to see what I get.

Standby....

Again, I have been wondering... guess its time to do as Mel suggested and get out my DF loop.

> The fact that several rigs died at once suggests a massive power line
> surge or lightning strike.

Well, that could be, but at this point I think there were different reasons why each one took a hike. In the case of the TS-820S, I think a problematic bandswitch coupling let go.

In the case of the TS-940SAT, the AVR board had more than one problem, most of which I have fixed. I also installed that crowbar circuit on the AVR board so I am less likely to lose driver transistors in the future.

I just have to reassemble the '940 and test. Right now, both I and my wife have been clobbered with a really bad virus. I'm not doing much in the shop right now.

Hmmm.....that DOES bring up a couple of interesting points: our Fisher and Paykel washing machine which is computer controlled, is having what looks like computer problems. And there are other things.

Conditions: Antenna tuned to resonance in the bottom section of each band.

FT-890: IPO activated (RF amp off) Mode CW

20 meters, CW wide (2.4 KHz bandwidth) - S-2: CW narrow (500 Hz bandwidth), S-1

30 meters, CW wide S-5, CW narrow S-2

40 meters CW wide S-6, CW narrow S-1

60 meters CW wide S-6, CW narrow, S-2

80 meters CW wide S-9, CW narrow S-6

Didn't try it on 160 yet, as I don't have my base loading coil installed and can't resonate the vertical there yet.

Conclusion: markedly more noisy on 80

The PEX does weigh less than PVC, but it is considerably more flexible, so care has to be taken that the ropes are not too tight and try to compress the PEX. I used a couple of zip ties on either side of the PEX on the 80M wire and then used some epoxy putty on both sides over the zip ties. I left it float on the other wires and ropes. It has held up so far.

Hi Scott,

Your link with the photos is really useful and helps me envision how I want to hang my new antenna. I had not considered using PEX water tubing, but it sure looks like a good idea. Can I assume PEX weighs less than PVC? Also, what keeps the PEX tubing from moving on the wires?

I forgot to mention what I used as spanner spacers. I used /2" PEX water tubing. Super cheap and very light weight. You cna find it in 10' straight sections if you look. You can buy it in a roll as well, but then you ahve to heat it with a heat gun and work it back to being straight, which is more time consuming, but can be done. Care has to be taken get the rope tension just right so as not to cause the spanners to want to bend. And for the record, the tension ropes are the most difficult part of putting a fan dipole together, if you want widely spaced wires; greater than 12" spaces at the ends.

Scott,

My apology I have not responded until now. I've had several versions of fan dipoles (all hombrew) and the last one I built has been on my tower for going on 3 seasons. I have posted photos of its construction here. I got this basic design from another ham on the internet through a Google search some years ago and modified it to make it work for me. The photos are before anything else was on the tower.

https://groups.yahoo.com/neo/groups/ham-antennas/photos/albums/309889546

This dipole has wires for 80/40/20/10 and is resonant on 15 on the harmonics of the 40M wire. Each wire is about 6" from each other at the feed point and is wrapped a couple times around the 6 gauge solid and then twisted back on itself and then all soldered (via propane torch) to that 6 gauge solid behind the 3/4" PVC and pipe conduit and fittings. Once it was all soldered, it was sealed and then pushed into the PVC conduit. The wires pass through the PVC conduit as holes are drilled through it, so it is the PVC conduit that holds the wire tension. By separating the feed points, it makes tune up much easier with less interaction. I used a 1115 unun because I already have several of that design. Certainly using one with studs would be easier to wire into the feed point, as I have to make a little custom coax jumper and seal it up on mine. The wires are spaced by around a foot out at the ends. It covers all of 40/20/15/10M below 2:1 and on 80M, is below 2.5:1 through the entire band. (I attribute the wide bandedness on 80M to the capacitive loading of the other wires.) The lower piece of PVC that sticks out the bottom was for use on a field day (for which it was originally built) and I don't use that any longer and it isn't anything you need if you are only going to hang it... although I found that PVC stub came in handy to secure the coax to to keep the feed point from moving due to wind. I really hadn't intended on making this a more permanent part of my antenna system, but I liked the way it performed, so I did.

Sorry, I have never modeled it and I am pretty good with EZ-NEC. Dealing with the feed points in EZ-NEC would be a challenge. I really should model it to see what it looks like in theory.

Hi Paul,

Great minds must think alike. I contacted Bob via email and he recommended an alternative configuration to support the balun and strain on the eye-bolts. His recommendation was the Model 1116d (better for lower frequencies) mounted to the DLP5 Dipole Plate. I will likely purchase the 1116dt (studs on top) with the DLP5 for my configuration.

Thanks for the good ideas on hanging the antenna from the tower. Now I need the weather to improve (stop snowing...) for this next project to begin.

Hello again Scott:
I took a look at the place from satellite view. It appears as though the tower is situated pretty much center of the lot behind the house with a thick stand of hardwood trees as you go further away from the rear of the house. Looks like the lot is more deep than wide and you have houses on either side. There are a few trees that appear to skirt the side property lines on both sides. Since the law defines ownership as vertical space, they may be jointly owned with the neighbors. If the base of the trees is on your side, you do not need permission to attach an antenna to them of course. Hard to tell from a vertical angle looking down, but most trees appear to be as tall or taller than the tower. To go with a non parallel configuration single feed, I think someone on this forum, or it could have been my club forum, mentioned to not have arcs of each element pair less than 45 degrees and try to go 60 degrees if at all possible. This would bring up a mounting situation for the balun to maximize the angles, as you may have to get the balun, also being used as a center insulator, away from the tower 2-4 feet. I would not know if hanging it from some galvanized strapping bolted horizontal across the tower (so the strapping would have two bolting points) would create interaction issues, or whether some heavy duty PVC would be better to prevent that. In either case, you would most likely need to go with a three eyebolt balun which is the same price. It is obvious considering your band choices why you thought parallel fan. Stacked parallel individual feeds would be a problem. Adjacent does not work considering the band choices, as again, not enough separation room side to side. In addition, the fan configuration would leave one entire side of your property to do something else on the higher bands. As a final thought, digest the information from all of the good suggestions the great group of hams here have thrown out, go to Google search, plug in your address, zoom to cover your lot and a bit of your neighbors as well so that the property lines are evident, hit screen print key on your keyboard, then open MS Word or Paint and right click paste or control V, (you may have to resize the image to make it fit) attach it to an email to <mailto:bob@...> bob@... (If you need help on the computer side, contact me off list, and I will put it together for you or send it to Bob on your behalf.) Be sure to be brief yet cover your needs, in particular balun mounting to prevent interaction. In a fan configuration, this will be a heavy antenna due to length/drop angle/resultant stress. Bob may have a mod in mind he could do other that the standard eyebolt which would be a worthy additional investment. I wish you luck and let us know how this works out in the final result.

I hope you don’t mind me jumping into this. I used some split PVC conduit for my spacers and used a dab of epoxy. Most of them did not make it thru the first winter. I then reinforced the location of my spacers with a small length of 22 ga wire soldered to the main upper support wire.

For my fan dipoles I always cut them a bit short.

THEN AT EACH END, I attach a short drop wire near the insulator. It makes it very easy to adjust tuning by simply folding the drop wire back onto itself. Once tuned, you can clip or tape the drop wire. Thus there is no need to constantly move the end insulator.

Dale,

I honestly
don't have the lengths. I started with standard
theoretical lengths plus
and extra couple of feet. HOWEVER, if you are in no
hurry, I can get them
for you. The whole things goes up and down an a pulley
very easily.
A friend of mine wants to tune a trap dipole in a couple of
weeks and wants to
use my tower to do it. So if you can wait, I'll
take some exact
measurements of everything when I bring it down and post
then. If you
haven't heard from me in a month, shoot me a reminder
via a private
e-mail.

Hi Kenneth,
I have a 43' vertical & a 173' endfed wire. The vertical & the endfed are pretty quiet. I hear everything that others hear on similar antennas, dipoles, G5RV's etc. & often more. Sometimes the vertical gives a better s/n ratio. Verticals don't have to be noisier. So, I would first investigate where the noise is coming from. Maybe just string a longwire and see if your noise is any better. I wouldn't spend any money until I spend some time trying to understand the noise issue. You might be wondering why you spent the dough. - 73 Bob

Subject: [ham-antennas] RE: Creative designs corp antenna company in japan

That would work well. The problem is I'm limited in space and this v dipole covers the lower bands and has excellent reviews. It's counter part which covers 40mand up (this covers 80m and up) got a 5 out of 5 on eham. I rarely see that. Doug Kb2uka

Hi OM,
My first thought was to check the receiver for internal noise. Do you also have a high noise level on a portable AM radio (are there any still out there?). Sounds like arcing. But when I read about all the stuff having possible electrical mains problems, I thought perhaps you should check, with an accurate meter, the two 'phases of your 240V mains. One might be a couple volts above the other from a poor neutral return. And check every connection in your main panel - tighten them all and smear anti-ox on the aluminum leads. Try your AM radio near your panel, too. Can you operate from a battery?
Terry

Well, there is also a 40 db over S-9 periodic arcing. Maybe from the same source. Guess I'll go looking as soon as I'm over this cursed virus.

I agree the Butternut is a very good option if you don't mind all the coils hanging about. I have an HF9V and it works just great.
Another option is the trap L. Total length to cover 10-80 would be about 54 feet. Of course you would need some kind of sky hook like a tree etc. Another way round that would be to put up a flag pole and run the wire through that. Not seen it used over here as we don't tend to fly our flags, in fact the law only permits our flag to be flown on certain days, silly but that's another story. With this antenna there is no matching issues. It's straight in at 50 ohms.
I have been playing with a 160 version with another trap in it and the performance with the vertical element only 20 foot is really good on all bands, even 6 metres.

If you are using really long runs of window line/ladder line say in excess of 100 feet and especially with higher transmit power of 500 watts or more the 300 ohm line will have more heating and power loss than the 450 ohm line. And open wire line will have less loss than window line.

It's a function of the width of the two conducting wires apart (spacing) and the amount of plastic insulation that lies between the two wires. Allegedly 300 ohm ladder line/window line will provide an easier match with a balance antenna tuner than 450 ohm.

Then there is the issue of visibility and wind catch (sail). The 300 ohm window line/ladder line is the winner in those two categories.

I have used both 300 ohm and 450 ohm line on a myriad of antenna types from dipoles to end fed wires to loops to verticals. Also a myriad of balanced antenna tuners such as the MFJ-974HB, Palstar BT-1500A and Johnson Viking Match Box and have found no noticeable appreciable differences in tuning.

The exception is with the tuners. I have found that the MFJ-974HB provides the easiest match across the largest span of operating frequencies, followed by the Johnson Viking Matchbox. The Palstar is the loser as far as matching range, especially above 17 meters but it does have the least amount of power loss.

I thought QST did a comparison with several tuners and the Palstar came out to have the best range.
Perhaps my memory if wrong and it was the most energy efficient .
I will have to look up that article. The article was in QST within a year or so .

Hi all,
I would like to share with you my YouTube video showing a Yagi antenna setup for 10 meters.
I used the Buddipole 6 meters Yagi Kit and two extra arms.
See the video: https://www.youtube.com/watch?v=LNVY7OyRoiA
https://www.youtube.com/watch?v=LNVY7OyRoiA
The montage takes on average 10 minutes.
It is really an excellent choice for portable operation.

31564. Vertical On Slope

Yahoo group: ham-antennas (2014)
Date: 2014-03-04 21:34:06 UTC
From: Kevin Kleinfelter
Topic: 31564 Message: 31564

I'd like to try a ground-mounted vertical. (I've got enough fear of falling that I just can't work up on my roof.)

The part of my lot which is away from power lines has a significant slope at about 20%. If I use ground-level radials and a vertical antenna, I'm not going to have a consistent angle between the radials and the radiator. Is 20% inconsequential? Would I be better off tilting the radiator to be perpendicular to my ground plane? Is a vertical simply impractical if you can't get a level ground plane?
TIA
Kevin / K4KPK

I sure miss the old days. 1970's and early 80's.

Every band was S=0 it never rose above that unless there was a signal or lightning. That's IT!

But of course this was living on a Farm, closest neighbor was about a mile away. No computers, no plasma TV's etc. Even the AM broadcast band was quiet.

Looks like you're right, Dave. 20 db over S-9 on 80 meters. This is in addition to that periodic arcing the really wipes me out.

I dug out a small AM/FM/SW radio I have here and by rotating the radio, I can get the noise to peak and null. Trouble is, I cannot remember what the directional characteristics of a loopstick antenna are.

The "stick" is mounted horizontally inside along the top of the case, with the winding perpendicular to the long side of the case, or at 90 degrees to the "stick" since the coil is wound around the "stick".

If I am correct in my thinking, the null should be parallel to the "stick", i.e. off the ends, which would make it broadside to the loop/coil. So, if I "point" the radio at the source, it should null.

Am I remembering this correctly? Someone please correct me if I'm wrong.

(I and my wife are fighting some really terrible virus right now, and I am not thinking very clearly. We're sicker than we have been in years.)

From: Artek Manuals
Topic: 30541 Message: 31567

Null is parallel to the stick, max broadside

Take a local map ...draw a line in the direction of the null.

Next drive a couple of blocks roughly perpendicular to null line and take another null reading draw a line along the 2nd null, where the two lines intersect is the rough location of the source. The more readings you take the better the pin pointing of the source. A portable 2M AM receiver (not FM !.... I use a cheapo Radio-Slock scanner) and 4 ele 2M yagi will allow you to pinpoint the noise to an insulator or transformer or faulty door bell transformer in someones house. The LF AM receiver has one draw back in that arcing transformers can conduct their noises for miles along the power-line, the 2M approach is better from this view once you get close. Think of it as trying to fox hunt a 2KW Spark Gap xmiter with the power lines as the antenna 8^). One of the criteria I had when searching for the current QTH was underground power lines

Good luck

31568. Dipole radiation question

Yahoo group: ham-antennas (2014)
Date: 2014-03-05 03:50:30 UTC
From: <dcerrato1@...>
Topic: 31568 Message: 31568

All, A regular dipole radiates broad side of its elements, so a dipole pointing north and south radiates west and east. An inverted v radiates at it's points, so if it's pointed north and south, it radiates north and south. What about a rotatable dipole configured in a "v" configuration? A regular v, not inverted. How would that radiate? Thanks Doug Kb2uka

Oh I wish we had UG power lines here in Seattle... If you want UG, you have
to pay big $$ and even then, the rest of the neighborhood will most likely
have overhead lines. :(

An V antenna (inverted or not) has "some" radiation off the ends but the majority of the radiation is still broadside off the sides. The end radiation at moderate heights is slightly better with the inverted V as compared to an upright V. The other difference is that the end radiation from the V's is vertically polarized and the broad side radiation is horizontally polarized. This only makes a difference in line of sight communication (typically VHF and above) with HF antennas which communicate largely through reflections off the ionosphere this is largely inconsequential. The degree of radiation off the ends is a function of the included angle of the V. For modest ange;s (90 degrees +/- 30 degrees) the end radiation increases as the included angle gets sharper

31572. Re: [ham-antennas] Noise level by band - loopstick pattern?

Yahoo group: ham-antennas (2014)
Date: 2014-03-05 05:25:34 UTC
From: Artek Manuals
Topic: 30541 Message: 31572

In my particular area (heavily wooded) I am told that the amount of outage and repair time due to tree limbs on the lines was the deciding factor. It was cheaper in the end for the power co-op to bury the lines than to send crews out 6 times a year to replace a broken line. The machine that they use to bury lines is an amazing piece of technology. It basically drills horizontally for 100's of feet leaving the surface undisturbed ...

No,
An inverted VEE is pretty well omnidirectional. Broadside to it's elements like the regular dipole it is more or less horizontally polarized. and radiates broadside to the wires.

But off the ends instead of the Null that is typically found there in a flat dipole. you have a vertically polarized wave leaving.

From: <dazzmos@...>
Topic: 31568 Message: 31577

In my experience I don't think you need to worry although the radiation does not go out the ends, if you look at the radiation pattern from side radio waves still go upwards from the ends of the dipole at approximately 45° so you may not get someone closer to you but you will get someone further away

As a matter of fact, the U.S. Army did considerable research on this. I may be able to find the report on it or perhaps I can point you toward the report.

Also, a couple of the guys on the 600 Meter Research Group who have experimental licenses in the 472 KHz region have experimented with those too.

One fellow built a large coil around a tree to inductively couple the output of his transmitter to it. I think that was Ralph Hartwell W5JGV. He wrote up his experiences with it, and posted that to his website. If you search on W5JGV or on 500kc.com you should be able to find that info.

He called it his "Tree-Tenna".

From: Kenneth G. Gordon
Topic: 31579 Message: 31582

OK. Once I have tracked down and "killed" the 20db over S-9 noise level I am presently experiencing, I would like to attempt the installation of a horizontal loop here.

From what I can figure out so far, it will be 50 feet long on the short sides (E-W) and about 100' on the long sides (N-S), making the total length 300 feet or 91.5 meters.

I think I can get it up to about 25 feet, which to me, means that it will be an NVIS cloud-burner. Not sure how much good that will do me.

I have about 100' of 450 ohm open-wire line, and am thinking of feeding the antenna at the NW corner of the loop, since that would be closest to the shack.

I also have an excellent balanced antenna coupler I built and used with my VanGordon All-bander about 40 years ago using very wide-spaced capacitors and large high-current coils taken out of a Wilcox 96A.

So, what does the collective wisdom think of this? Am I barking up the wrong tree?

Well, you didn't say what frequencies you will use it on, but up to 60 meters it is NVIS and omni. Above that it get multi lobed. A lot of work for not much improvement over any NVIS antenna.

Mel, K6KBE

On Wednesday, March 5, 2014 10:12 AM, Kenneth G. Gordon <kgordon2006@frontier.com> wrote:

What about a jpole but radiator made from a metal tape (you sure know the metal tape yagi that others use for foxhunting)

I like the idea of using the walking stick approach. It will certainly carry any jpole etc. And if yours is like mine with a metal point on the end, you can drive it into the ground nicely. A thought.

Well, my present 55' vertical is not an NVIS antenna. I use it on 160 meters
and up.

As a matter of fact, the U.S. Army did considerable research on this. I may be
able to find the report on it or perhaps I can point you toward the report.

Also, a couple of the guys on the 600 Meter Research Group who have
experimental licenses in the 472 KHz region have experimented with those too.

One fellow built a large coil around a tree to inductively couple the output of
his transmitter to it. I think that was Ralph Hartwell W5JGV. He wrote up his
experiences with it, and posted that to his website. If you search on W5JGV or
on 500kc.com you should be able to find that info.

He called it his "Tree-Tenna".

Quickie small packable 2m dipole - If you have old TV stuff laying around, look for a set of telescopic rabbit-ears they used to include to stick in a hole in the top of the set. Take off the twinlead & hook coax shield to one side, center conductor to the other (usually whips are secured w/ screw & nut into plastic base). Extend each whip to about 19" or so and mark.

I have my loop at abut 85 ft (550 ft loop) and it appears to have a lower angle of radiation, than when installed at around 30 or 40 ft. The DX capabilities on the higher bands are exceptional.

Good luck

My impression is that barring the sort of fields that exist near
a stellar-massed object, radio waves are unaffected by gravity.

So a vertical that is "vertical" on a slope is the same, electrically,
as a tilted vertical on level ground.

A vertical that is perpendicular to tilted ground can have a very low
radiation angle, even negative (with respect to the horizontal) in the
downhill direction.

There are remarks also about horizontal antennas.

In my particular case, the downhill angle points towards Europe.

For 2m, I like a 1/4 wave whip with a dangling "tiger tail" (wire counterpoise attached to shield). For APRS tracking, I have a pocket in my backpack with a tiny hole in the bottom and an open top. With the HT in the pocket, the whip extends out the top and the wire dangles through the bottom.

Of course, when I use it handheld, the wire just dangles in front of me.

This works pretty well, unless you want your antenna up at 30 feet. Then you have to reach really far to engage PTT. ;-)

I had a butternut HF6V on a 55 degree slope at 210' to near sea level and it worked great. I think you will find benefit from the sloping terrain from a DX perspective. Benefits include benefits in lower takeoff angle. I had my antenna elevated at about 8' and used stub tuned radials. So that could have made a difference. You are definitely asking the right people here. My results are anecdotal.

Quick effortless way to get height for a little antenna like this is with a Jackkite pole. You can get them that telescope out to 28' from about 4' and they are relatively light weight.

James "Jim" M. Geidl, K6JMG

Yahoo group: ham-antennas (2014)
Date: 2014-03-06 00:05:23 UTC
From: Mel Farrer
Topic: 30541 Message: 31604

Somewhere on a ocean trip I bought a Sony AM/SW radio that fits in the palm of your hand. Goes to 18MHz. Has both a lipstick and a telescoping whip. I can attest that the loop-stick has located several noise sources using the null. I even put a sticker on the back to indicate the null. Some sources were only in the AM band others quite narrow in frequency. A thought.

As a matter of fact, the U.S. Army did considerable research on this. I may be able to find the report on it or perhaps I can point you toward the report.

Also, a couple of the guys on the 600 Meter Research Group who have experimental licenses in the 472 KHz region have experimented with those too.

One fellow built a large coil around a tree to inductively couple the output of his transmitter to it. I think that was Ralph Hartwell W5JGV. He wrote up his experiences with it, and posted that to his website. If you search on W5JGV or on 500kc.com you should be able to find that info.

He called it his "Tree-Tenna".

I dunno guys. A lot of bad reviews for Jackite.
You can buy two gray plastic conduits 1.5" diameter that will telescope together and form a sturdy 20' pole to support wire antennas or a vertical, from Home Depot. They are $2.00 and change each! A lot less expensive than a Jackite and probably a lot stronger in a wind.

You must get it high enough to be 1/2 wavelength on the fundamental frequency to make much difference.

Mine is 20' and the plots I have for 20&50 are not significantly different.

I have a Jackite. I have a German mast of the same length, but much shorter when collapsed. I also have two carbon fiber masts. (Hi. I'm Kevin, and I have an antenna mast problem.)

If you want a 30 foot "parking lot portable" mast, the Jackite is fine. If you're going to carry it 5 miles up the side of a mountain, it is awkward and heavy. (Been there. Done that.)

I'll probably sell my German mast, because I use the CF masts when I carry a pack, and I use the Jackite when parking lot portable. The Jackite is stiffer and goes up faster than the others.

None of them are stiff enough to support more than a simple wire, IMHO.

Ok, final solution, I think at least for us camera geeks. I carry a tripod, for still shots and it is very light and compact. If you rotate the platform to a vertical position, WA LA you have a base mount for any 2 meter antenna you want including a gain vertical. Yes, I had to fabricate a clamp, but that was easy. Now I have a dual purpose tripod.....

From: Paul V Birke PEng
Topic: 31579 Message: 31614

not sure Chris

there is a USA patent with a Rogowski coil belt to induce current in the tree

makeshift antenna for sure

the Rogowski coil makes a circulating magnetic field around the trunk that induces the current

https://www.google.com/patents/US3646562?dq=tree+trunk+antenna&hl=en&sa=X&ei=9_EXU-OjCIXayAHS1YD4Cg&ved=0CDoQ6AEwAQ

we used to use Rogowski coils to measure stray currents flowing in very large power transformer cores, I mean stuff that was 24" to almost a m ie 40 in diameter in the heavy electrical industry. You could easily make one using phone coiled cord AS LONG AS YOU MAINTAINED A UNIFORM TURNS/CM OVER THE WHOLE CIRCUMFERENCE

the current is obtained from first principles !

BTW: Rogowski was a GE Engineer and I only a humble Westinghouse Engineer
I only knew of this use as I had become part of a GE plant here in Canada. Rogowski was a very smart dude for sure. There is a Rogowski electric field profile named after him as well, likely other things as well. *****end of minor history lesson*****

best Paul

The metal spike and/or copper coil and unbalanced coax feedline does all of the radiating. The tree does not radiate, it just acts as a very large insulator.

Hi Dave...

This is just a statement of personal opinion....
If your actually going to spend money on a modeling program, then go with a "standard" that has lots of support and been around for a while.... EZNEC. If you don't want to spend any money, but still get support from the "community", then go with 4NEC2. Both programs are NEC2 based. EZNEC also has a NEC4 option, but besides the cost of the program, you have to purchase a license from Lawrence Livermore Labs. Last I heard, it was about $600 and anyone not on American soil need not apply.

Judging from the picture, seeing the long thin, low Q, base coil, it doesn't appear it would be very efficient. It would be very inefficient in the low bands.

Maybe not much more than a resonant dummy load on 80 and 40 meters.

From: Kenneth G. Gordon
Topic: 31623 Message: 31623

This morning, I connected the FT-890 to a car battery, then switched off the main breaker to the entire house.

Result: no change. Still 20 db over S-9 on 80 meters. Switching off the RF Preamp reduces the indicated noise level by less than 10 DB. Switching in the NB reduces the noise another few db, but introduces severe distortion as the NB control must be set quite high in order for it to have any effect.

Conclusion: noise is not "local" in that it isn't within our own property.

I have also discovered yet another "interesting" noise: some sort of very unstable RF carrier that periodically sweeps the entire length of the 80 meter (at least) band at +30 DB over S-9, beginning low and sweeping high.

Have not yet figured that one out.

Heading out today with a portable receiver with loopstick. The noise is SO LOUD, that at this point, all I want to do is to try to determine direction. Therefore, an AM radio will suffice.

One source of sweeping carriers are the Ionosondes. It used to be 30 years ago that the number of sweeps it did varied by calendar day. Standard was every quarter hour . Special days every 5 mins. with high,medium,low power at quarter hours IIRC.

These day they use more sophisticated digital types but I haven't any recent experience.

What I worked with was class A push-pull paralleled 815's putting out 10Kw? pulses to delta a/e.

Cheers

31629. Gyroscope on antenna mast.

Yahoo group: ham-antennas (2014)
Date: 2014-03-06 23:14:45 UTC
From: <jim.geidl@...>
Topic: 31629 Message: 31629

OK, upfront, I realize that this is really really off the wall. If you have an object, like a tire, spinning horizontally it wants to stay spinning horizontally. If the shaft in this "tire" was your mast pipe and the tire was up the pipe towards the top and forced to spin, maybe with a motor, would it hold the mast pipe vertical without guy wires?

That is VERY "outside the box" thinking. My heartiest congratulations. :-)

However, in my opinion, if one could overcome the mechanical difficulties in mounting such a flywheel, there is also the problem of "precession" that all uncorrected gyros are subject to.

What I suspect would happen is that it would hold the mast upright for a while, but with no correction-input, it would eventually fall.

In addition, I am sure there would be some sort of interaction between the size of the flywheel, the height of the mast, the weight of the mast, the input power required, and possibly other factors to consider.

Very well done, however. Keep it up. I really like this idea and this sort of thinking.

It has been my experience that if the noise is louder on a higher frequency than on a lower frequency then it is close to very close (within a block or so).
A noise that is louder at 80 or 160 meters can be literally miles away! When I lived in WV I wound up taking the power company to court over the noise problem I had and finally got everything cleared up.
In your case I expect it to be a good distance away.
 What does it sound like on 15 and 10 meters? If it's relatively quiet it's probably not very close.
If you find a pole that seems like the problem write down all the numbers you find on it and report that to the power company if it is a utility company problem.
73 and good luck.

Subject: [ham-antennas] More on noise...

This morning, I connected the FT-890 to a car battery, then switched off the main breaker to the entire house.

Result: no change. Still 20 db over S-9 on 80 meters. Switching off the RF Preamp reduces the indicated noise level by less than 10 DB. Switching in the NB reduces the noise another few db, but introduces severe distortion as the NB control must be set quite high in order for it to have any effect.

Conclusion: noise is not "local" in that it isn't within our own property.

I have also discovered yet another "interesting" noise: some sort of very unstable RF carrier that periodically sweeps the entire length of the 80 meter (at least) band at +30 DB over S-9, beginning low and sweeping high.

Have not yet figured that one out.

Heading out today with a portable receiver with loopstick. The noise is SO LOUD, that at this point, all I want to do is to try to determine direction. Therefore, an AM radio will suffice.

There are solid-state ICs that combine 3-axis accelerometers, 3-axis gyros, and magetometers. Here's an example:

Triple Axis Accelerometer and Gyro Breakout - SparkFun Electronics<https://www.sparkfun.com/products/11028>

Here's another:

https://www.adafruit.com/products/1032

I've been thinking of coming up with a portable satellite-antenna positioner using these devices. Control of a boom or other directional antenna would be even easier. That's rotational movement in a single plane. Combined with a magnetometer, a system could be self-correcting in that it would find magnetic north on its own, and you'd just have to program in the magnetic declination at your location.

Very cool stuff!

Gee, Tom, that info is somewhat discouraging: the noise does get much weaker as
I go up in frequency.

However, even on 10 meters it is a significant annoyance.

I'll take some better readings by band to see what's what.

In the meantime, I have printed off three different resolution maps and will
start driving around tomorrow to see if I can DF this crap.

There is a very interesting site by a ham in (I think) Finland on tracking down
and eliminating noise. I'll have to revisit that site...if I can find it again.

Thanks, Tom.

80M noise- s9+20..

I'm no expert on 80M but isn't that band typically noisy s7 or so.
I assume you've determined the noise sounds like man made and not atmospheric noise?

Maybe at that time of day it should be quiet?

I have the equivalent antenna from MFJ.

Mobile antenna is a misnomer unless we have that US/UK language difference again.

Portable would be the definition I would use. This antenna isn't going to survive if there is wind blowing at highway speeds.

The fellow I bought my rig and antenna from says the instructions are incorrect on the antenna I have, but with an antenna analyzer or other antenna measuring device you can figure out the correct jumper settings rather easily.

Well, 80 is certainly normally noisier than, say, 20. But this level of noise is not normal

> I assume you've determined the noise sounds like man made and not
> atmospheric noise?

Yes. It has a periodicity that sounds very much like 120 Hz., although I have not yet checked that out closely.

> Maybe at that time of day it should be quiet?

It is on at the same level, or very nearly the same level, 24/7/365.

I am positive it is man-made.

I went out with an BC AM receiver with a loopstick a few minutes ago. There is one of those orange sodium-vapor (?) street lamps right across the street, about 40 feet away, from our front door. It isn't working.

However, this interference does not come and go either.

I didh't find any single source of interference using the BC band receiver, but loads of them. However, none of those sounded exactly like what I am hearing on the communcations receivers either.

I'm afraid I am going to have to fire up the Stoddart NM-20 150 Khz to 25 Mhz. or the NM-30 VHF job, to find it.

I'm not pleased.

Don't forget that a live tree trunk is full of nutrient rich liquid (sap), which, like most living things, can make a pretty good electrical conductor. So to say that a tree is nothing but an insulator, is somewhat ignorant.

Good conductor? I wouldn't know that. But a tree trunk is a heck of a lot of conductor cross-section.

Bark OTOH does not make a good conductor, which is why a wire antenna can rub against it and not be shorted out.

Andy

The loading circuit merely acted as an unshielded radiating dummy load...the tree did not add to the radiation...in fact, it may have shunted some of it to ground (as mentioned earlier)...a loading coil around a tree is NOT a coupling link...it is a high Q small antenna...high losses and narrowband...and high ground losses..

You can "load" anything up with the right circuit..does it radiate is the big question...those who claimed to have loaded up trees could have cut the tree down and still have the same signal output!

Andy & Chris
I uploaded a file (Filename TREE) to the files section which describes US
Army research loading up a tree in 1973.

They concluded that a tree was better than a vehicle whip.

Sure, if you had a loop or a loopstick antenna.

Trouble is, most noise seems to peak around the BC band...or lower.

Therefore, you might end up like I did with so MUCH noise, it would be
difficult to pinpoint the one that is bothering you the worst.

Loops are relatively easy to make, though.

I use a similar antenna, it is called opek, and I have worked three countries sitting on a Blue Ridge Parkway overlook on a Sunday afternoon with around 50 watts. They can work on mobile, but you want to take the Wander lead off when you're driving. it can probably get blown off by a stiff breeze. 73 de KC4BO

31648. Noise level by band

Yahoo group: ham-antennas (2014)
Date: 2014-03-07 05:16:54 UTC
From: Kenneth G. Gordon
Topic: 30541 Message: 31648

OK. Here are my readings from the S-meter on the FT-890, with the antenna system tuned to resonance and the rig tuned up on all the bands which I have listed.

80 meters RF amp on - S-9+20db
RF amp off - S-9+10db

40 RF on - S-9+10db
RF off - S-8 to S-9

20 RF on - S-8 to S-9 (peaking S-9+10db)
RF off - S-4 to S-5

15 RF on - S-5
RF off - S-1

10 RF on - S-2
RF off - S-1

On all bands I can hear a constant "crackling", even on 10.

Ken W7EKB

4NEC2 also has a NEC4 option if you get the license from the Lawrence lab.

Hi- I have S+20 over every morning on 80 mtrs. Switch to the vertical and drops to S-9- 120 hz- Can you shut off everything except the rig and see waht that does. I had 2 qrns here - Reported them to arrl state- Said they would help ?? Found one on 40 to be the new cable phone ps- They can out and checked for rf - Yep,so gave me a new one- The other proved to be a router- 2 back- Changed that out ,for other reasons and qrn gone !!! Got rid of all me crt type monitors and that helped some - No easy tack,but can be cleared!!Hope you get it !1T.C. Jerry W8KQ

Yes, he ran his rig on battery power and shut off main breaker with no change to noise level. The source is not on his property.

Rumor has it beware of AT&T Universe. A ham on another site said the installer declined to install after finding he was a ham.

Plasma TV two or three houses away can make s9.

There's more and more noise generators all the time.

Touch lamps, dimmers, faulty doorbell transformers, modems, computer controlled appliances, and more.

You guys remember the landowner in Florida threatened with a fine because his water well was a incidental radiator?

All this reminds me how lucky I am.

This is the coding mechanism used for humanoid (and other) robots to keep them vertical. A more common place that you will see it is in things like the Segway. We have adolescent kinds in our robotics group that are doing it, it has become that common.

Ahh grasshopper... the zen of Bumper mounting a tree is simple

1) Pick a tree with a clear path to it at least a mile long
2) Drive towards the tree as fast as you can. At speeds above 50MPH (80 is better) the bumper and the tree will become one upon contact.

Noise on the bands. An often overlooked source of noise is the GENERIC power supplies/battery paks used for laptop computers. Some of the cheapo, Brand X power supplies generate a tremendous amount of spurious RF, even when the laptop is not plugged into the power supply. If the power supply is just plugged into a wall outlet, and not connected to a laptop, it is idling and sends out LOTS of RF. The same goes for cheapo cell phone rechargers. If they are just left plugged in, the amount of RF is incredible. Look around your house, and see if family members, especially youngsters have left any power supplies,chargers plugged in the wall. Unplug them, and you might be pleasantly surprised.

Good luck 73 John

I was hunting for a DF loop yesterday for noise hunting and I came across a web page for a Dutch ham's adventures in hunting noise around the area of his house (in some cases up to 2km away). It's a very interesting (and in some cases amusing). If I can find the page I'll post it here.

Hi.

I feel up to modelling an aluminum tree with up to three arbitrary straight branches. :-)

Seriously, given conductivity, capacitance, inductance data, it would be possible to do a fairly decent job of it. But not me...

Bolt the pot on the bumper, fill with soil, insert tree, place ground wire
from pot to frame of car. Stand back 100 feet when transmitting.

Can you imagine loading up one of the redwoods in CA? Or would that be
illegal because it would exceed the amateur antenna height rules?

Try mounting it going *broadside* into a *Saguaro Cactus*.
It became one with the side of the car and we went another 40 ft.
The Arizona state fine for destroying it was real nasty though.

Something like $600 in 1964!

The 200' rule is primarily an FAA (registration) regulation which is also backed up and enforced by the FCC in the case of communication (amateur or commercial) towers/antennas. Basically the regulation requires registration with the FAA and FCC and certain clearance lighting requirements for any structure "200 feet or more" in height. Additional restrictions (lower) may apply depending on the proximity to an airport. The FAA requirements apply to ALL structures not just amateur radio antennas/towers.

31678. 80M Vertical needs a rebuild (wind damage) need ideas

Yahoo group: ham-antennas (2014)
Date: 2014-03-09 12:34:45 UTC
From: Goldtr8 (KD8NNU)
Topic: 31678 Message: 31678

Well I came back from being in Europe the last two weeks and my 80M vertical is now an inverted as in the EMT Conduit bent up to the point I can not straighten it anymore. It was 65 ft long and a real 1/4 wave and really worked well plus it was real cheap. But in the end you get what you pay for.

So I want to rebuild it but I need to do it with better materials and this time also I need to understand wind load calculations if I design it myself.

Clearly options are I could purchase online aluminum tubing or find local suppliers in Michigan or I can purchase a pre-engineered solution like from DX engineering. I don't want to use EMT again as its yield point is to low and the stuff bends to easy.

My target requirements are a 1/4 wave resonant for 80m band midpoint.
I have to be able to tilt it over when there are thunderstorms for extra safety. (My current tilt over works good so I have this engineered)
I needs to be strong enough for adding parallel wires for 40m and 20m and the vertical section for and inverted L for 160M.

So can anyone point me in the right direction for the load calculations so I can make some good choices for base materials if I don't go commercial route. Or maybe I should just go the commercial route if others have experience from their own endeavors in making verticals.

The other consideration is that if I can make something stiff or strong enough then in winter I could possible use some capacity hat on it and try 160m instead of the inverted L to see which could work better.

All I know is I sure miss it as there was lots of good DX yesterday evening on 80m and I could not hear anything on the loop and they should have been easy contacts with the vertical.

So just looking for ideas comments and experience with different materials so this time I get the total design correct.

The area around Wake County NC (Raleigh area) has a 100 foot rule in place for ANY Amateur towers. Apparently some neighbors of a ham with a 200 foot tower got excited about having towers in the country. HOA's have "No antennas other than a sat dish that is customer and ordinary" seems to have ruled the area.

Whether it complies with *federal* regulations doesn't matter to the dolts in county government. (They are more interested in saving the trees and water than complying with the law of the land...)

They "Grandfathered" in a few 200 foot (well, 190 foot) towers that appeared before they decided to leap into the regulation business.

There are worse places-- my apartment allowed a 30 foot stick in back....

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

Yes. That's it. I have visited his page too, and found it valuable.

FYI, I called a "special person" in our local power company's organization. He is coming on Tuesday with his special equipment to help track down the problem.

Keeping my fingers crossed...

There is indeed, or there used to be, a height restriction, of 200 feet above local terrain or something. Since I am unlikely to have a tower any time soon (or maybe in this life), I have not paid attention. I am sure it can be looked up.

Well, "there is" a 200 foot rule..at least one in Part 97, but it does not restrict you to 200 ft max.

Chris
WB5ITT

§97.15 Station antenna structures.
(a) Owners of certain antenna structures more than 60.96 meters (200 feet) above ground level at the site or located near or at a public use airport must notify the Federal Aviation Administration and register with the Commission as required by part 17 of this chapter.

Never was a 200ft rule .....

31687. Noise - more

Yahoo group: ham-antennas (2014)

From: Kenneth G. Gordon
Topic: 31687 Message: 31687

As I mentioned earlier, there is a very competent noise specialist from Avista corp coming down here on Tuesday to help me track my noise source.

In the meantime, I have discovered another anomally: periodically, at very irregular intervals, and continuing for very irregularly long times, the noise level drops at least 30 db and remains there for varying lengths of times.

When the noise level has dropped, on 80 meters, my ambient noise level then is about S-7.5, which from other info I have heard on this list, is about normal, although that still seems much too high to me.

31690. Zepp end-fed--how to set up?

Yahoo group: ham-antennas (2014)
Date: 2014-03-10 21:09:37 UTC
From: John Flynn
Topic: 31690 Message: 31690

Good Day Everyone,

After considering a few options, it looks like a Zepp end-fed antenna will fit on my lot most sneekily. I can orient it in pretty much in any direction (lots of trees), and have a few elevation options. I'd appreciate your tips and observations about how I should go about this project.

Tnx es 73

Vertical and then sloping down or in a vertical position. That's how I would have it if possible. The vertical way is great for dx. If you don't have room for it hung vertically then get the matching section up vertical and the rest sloping down to the ground this will still be good for dx.

Hi Ken,

It's great that you seem to have narrowed down where the noise is coming from but your work has just begun.

If your friends with the neighbors see if you can find out the manufacture and model number of the new furnace. Being electronically control it should have had to pass FCC compliance for radiation. You need to research if it was tested or not. Next if you are an ARRL member contact them to see if you can get some help to totally pinpoint the furnace and the best way to proceed in this case. If you have some friend or club member who owns a spectrum analyzer enlist their help to get field measurements of the frequencies and emission levels. Documentation is your next important step before you can make a complaint. The more you can present for evidence the better your position for getting this resolved. Also remember the old adage "you can get more flies with honey than vinegar" and it applies here because you may be bucking up against a manufacture that has money to burn to protect their product. I hope this helps you out.

I've had a problem with the old fashioned circle lights. Usually found in kitchens of older neighborhoods. I live in an old village and can turn a beam in any direction and find interference. I also have one in my apartment. I have also called the power company and had had them come out to fix a interfering transformer... It's been 2 months. And they have had to replace and repair multiple power poles and transformers. They are in the process of changing the street lights in the neighborhood as well.
Best of luck to find your problem.

We are friends. They are quite old, like in their 90s, and we kind of watch out for them.

They have told me who installed it. I called the local installer. They told me it was a Ruud. (?) I then told the installation folks what was happening and suggested they call the manufacturer to talk about this issue. I also told them that the FCC looks unfavorably on this sort of things and that the maker might be subject to fines.

What I did do was to first call our local power provider, Avista corp. Their noise expert came down this morning and using his detector walked all around for about 3 blocks in every direction. His unit pinpointed the neighbor's basement and the gas line that was coming out of the wall. I know for a fact that the furnace is in the basement fairly close to the gas meter, so that pretty much pinpoints it for me.

Date: 2014-03-11 22:11:35 UTC
From: Kenneth G. Gordon
Topic: 31702 Message: 31702

The service rep came out today and while on the cell phone with me, first unplugged the furnace....which made zero difference. Then he switched off the main breaker to the entire house. Result: zero difference.

Back to the drawing board.

When I set the FT-890 to AM, the sound is exactly like a giant motor, or even a radial aircraft engine running.

Rats!

Well, I am going to add a loop to the FT-890, take the whole mess out to the car, and try to get some triangulation done.

I am not a happy camper.

We are friends. They are quite old, like in their 90s, and we kind of watch
out
for them.

They have told me who installed it. I called the local installer. They told
me it
was a Ruud. (?) I then told the installation folks what was happening and
suggested they call the manufacturer to talk about this issue. I also told
them
that the FCC looks unfavorably on this sort of things and that the maker
might be subject to fines.

You won't get any support from the installer, all they care about is selling
systems. Since your friends with the neighbors, which is a big help, can
you look at the furnace and write down all the information on any tags
attached to it. One thing in particular to look for is any info on the tags
that says it meets FFC compliance. My guess is that you will not see that
on any tags because many manufactures are ignorant of the fact or just don't
care that they have to meet these requirements. On the controller for the
furnace especially look for a model number. I believe and maybe others can
chime in but there may be an online FCC database to check items for
compliance.

> Being
> electronically control it should have had to pass FCC compliance for
> radiation. You need to research if it was tested or not.

I'll have to find out about all this.

> Next if you are an
> ARRL member

I am.

frien
> d or club member who owns a spectrum analyzer enlist their help to get
field
> measurements of the frequencies and emission levels.

Now that you have the proof the measurement portion is the next important
step so that you have frequencies and db's to give the FCC if it comes to
that. But if you call the manufacturer and have this data it will make them
nervous and more likely to help correct the problem.

What I did do was to first call our local power provider, Avista corp. Their

noise expert came down this morning and using his detector walked all
around for about 3 blocks in every direction. His unit pinpointed the
neighbor's basement and the gas line that was coming out of the wall. I know

for a fact that the furnace is in the basement fairly close to the gas
meter, so
that pretty much pinpoints it for me.

Ken that is a great power company you have. The best part is now you have
an independent source pinpointing the source.

He could also work with his neighbor n contacting the mfg instead of being adversarial in this. Yes, the equipment is not in compliance, but saying so and leaving the neighbor to deal with it alone wouldn't make for a good living environment in the neighborhood. Also, if just left to the neighbor to deal with, probably nothing would be done about it.

Topic: 31705 Message: 31705

Hi group,
I am using the MFJ-969 antenna tuner 160m-6m
Works well 6m to 300w
I have a higher power application for 6m...
Has anyone tried the MFJ-989 on 6m? It looks like the MJF-969...
Wondering if maybe a mod for the MFJ.989 for 6m?
Or know of high power 160m-6m tuners?

Good afternoon all, I'm wondering if it would be ok to use 14ga solid or stranded thhn/thwn copper wire to make a 1:1 (or any other ratio) balun. Most likely I would be using ferrite toroids, but rods wouldn't be out of the question either. Max RF power would be is 100w.

The first balun I'm hoping to make is a 1:1 current balun/choke for a 6m moxon. I know I can just coil some coax at the feed point for a choke, but I'd rather not. What would the best ferrite mix be at that frequency (50.1 MHz)?

Any help is appreciated.

Thanks,

Geoff, NW7GM

Ken,

I took a cheap portable radio and hoofed it around the neighborhood until I found the source. I couldn't quite figure WHAT it was but knew WHERE it was. I called the power company and they sent out the buzz-bloodhound and found that there was an underground transformer that was leaking fluid and noise. They were actually pretty grateful that we had found the noise because they said the transformer was on it's way to an explosion. They replaced the transformer that afternoon and took my noise home in the truck with them.

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

31708. Re: [ham-antennas] Using thhn/thwn wire for balun?

Yahoo group: ham-antennas (2014)
Date: 2014-03-12 00:00:25 UTC
From: Artek Manuals
Topic: 31706 Message: 31708

I have made several Baluns and Ununs using 14GA solid THNN house wire. All tested and worked as expected. Depending on the application they are good to a KW . I have a 2:1 Unun made with this stuff at the base of my 160/80M inverted L that has never broken a sweat in the last 4 years at the full legal limit. I say depending on the application. I would not use it in a case where their are high voltages likely (say because of HIGH SWR) or situations where the core might get hot (marginal core size for the power used) . If your planning higher temperature or voltage operation then Teflon covered wire is a better deal . At 100W however I wouldn't wouldn't worry ibout it for more than a nano second.

Bill,

I didn't have any fancy dancy equipment to use. If I remeber right, the utility company told me to tune the radio to the upper AM stations to a spot with nothing but noise. It didn't take a lot of tracking to find the noise. I think the fact that the radio I had was kind of junk help because I wasn't picking up noise from any great distance so the closer I got the louder it got.

First, I went through the whole process of turn off the mains at my house to be sure it wasn't internal.

Date: 2014-03-12 01:39:29 UTC
From: Richard Schmuke
Topic: 31706 Message: 31714

I don't see why not, 14 gage is a real overkill for 100W. I make baluns and unun's out of magnet wire, Teflon covered wire (a real PITA)and my favorite is speaker wire for 1:1's or duel rod 1:1 made into 4:1's. The color coding of the wire helps for ID when you solder the ends. Mix for 50Mhz hertz slips my mind for the moment but color ID is Yellow for 50 Mhz, regular HF will be red.

Mainly cuz the service guy and I know one another quite well. We have some
Nagant pistols in common.

Don't think that happened, but since I am now building a shielded loop to go
do some serious tracking, I'll find out.

Narrow down the frequency band causing the problem and note the noise strength.

Try each band going higher in frequency

You know its a radiated problem because the problem is not on the power line.

Do you have catv service in your neighbour hood?

You also have to remember that the ham radio communications receiver have a much higher sensitity eg lower microvolts senstivity than the standard broadcast band receiver record levels each band.

Harmonics frequency levels get lower in level as the frequency gets higher eg try 29-30 mhz and work your way down.

Use your 2 metre hand helds and see if the problem exists try the low end of your fm receiver eg144 mhz fm band is involved

Remember the problem could be failing power insulators close by within a few feet of your house.

What part of the USA are you in?

Also try the ARRL technical folks there a really good resource and have years of experience.

Todays electronic world has created many more new noise sources.

Is this problem time of day sensitive.eg hospital xray equipment for example operating from 7 am till 9 pm for example

Looks at this point, like the noise is coming from our neighbor's new all electronic furnace.

Power lines absolutely silent.

More later.

Without some test equipment that is above my price range I don't know how to tell. I do my fine adjustment with a MFJ-259 and a carbon resistor. I have found out that if a design calls for 18 turns for a 7 to 21 MHz range you need to reduce a turn or two for 28 and 50 MHz add a turn or two for 160 and 80 range. Some of the best reading baluns I have made were from Russian military surplus rods bought from a Lithuania ham on E-Bay. The picture is of a 4:1 x 1:1 switchable balun I made for my incoming ladder line. One time I explained the right hand twist on one and left hand on the other to balance out the electrons but too many people don't understand tongue in cheek design.

Given that this seems to be a new install, a probable better way to deal with this is to talk to the installers company, let them know that you are in the drivers seat, and that it is best for their customer, (your neighbor), to solve this problem, prior to including Federal agencies in the fix.

Don't put it off... Act quickly, and make sure your neighbor is in the loop as well. Make this the installers/Manufactures issue. If you wait, it will only get more difficult to solve.

Keep a log of every discussion you have... Let the installer know that you are in the right, that you are not going to go away, and that this will only reflect on them poorly if not corrected. Be nice the entire time, but be firm. This is the installers job to correct. If they doubt that they are responsible go to the FCC web site and point them at any number of enforcement letters the FCC sends out. Remember, be nice the entire time, but keep VERY good notes.

31721. RE: [ham-antennas] Noise - source NOT identified.

Yahoo group: ham-antennas (2014)
Date: 2014-03-12 06:28:16 UTC
From: Michael Lodico
Topic: 31702 Message: 31721

Hi Ken,

This is really disappointing information. It sounded like you had found the source but it appears that the power company guy either did not know what he was doing or just out right lied to you.

Ken let's take this a step at a time. Can you put the radio in the car and tune in the noise and then shut off your main breaker to totally eliminate your house causing the problem? I see you live in what could be considered a somewhat rural area are there any hams in the area that could help you track this noise source down?

I just had another thought. Check with your friend the service guy and ask him if the furnace controller has a back up battery connected to it so it doesn't lose programming in case of a power failure. It's a wild shot but you never know.

When they put in the new furnace did the gas company change out the meter by chance? A lot of newer meters now allow the companies to just drive a truck through the neighborhood and they record your usage remotely. I wish I lived closer I would help you track it down but I hope these questions and suggestions help you. Please keep us all up to date on what you find.

73 de K1EG

Mike

The service rep came out today and while on the cell phone with me, first unplugged the furnace....which made zero difference. Then he switched off the main breaker to the entire house. Result: zero difference.

Back to the drawing board.

When I set the FT-890 to AM, the sound is exactly like a giant motor, or even a radial aircraft engine running.

Rats!

Well, I am going to add a loop to the FT-890, take the whole mess out to the car, and try to get some triangulation done.

I am not a happy camper.

Ken

31722. AW: [ham-antennas] Titan on lower band edges

From: siegfried jackstien
Topic: 31245 Message: 31722

As far as I know all other bands should be wide banded enough to also work well on the lower band edges ... but if you wanna "tune it" especially for lower ends then maybe you have to make the elements a bit longer (hose-clamp and some wire will do fine)

From: siegfried jackstien
Topic: 31702 Message: 31723

Maybe you have a scanner / air band receiver that can do am but on 2m ...
then you can use a tape measure beam and pin-point the noise easy

If you have a handheld am radio with internal ferrite rod antenna then you
can "null out" the noise (antenna receive less from its ends) .. so you will
see that you find 2 directions (or in other words one line) that points in
the direction of the noise source .... then .. walk a few houses in one
direction and to the same again ... and you have another line

Where both lines cross ... there is your source

(same with using a yagi on 2m am)

Can anyone find, & Make copies of these "Letters" Finding them on the FCC site is sometimes really hard to do. Maybe make copies and save them in the files area on the groups web site page?

From: worahm@...
Topic: 31702 Message: 31726

I have not followed the thread from the beginning so I apologize if this possibility has already been mentioned.
Many years ago, I discovered two "touch me" lamps in my living room that was causing noise in my Kenwood transceiver.

A touch- me lamp typically uses a chrystal cut for 3818Mhz.

I replaced the touch- me feature with an in-line, on/off switch and the noise disappeared.

I have thought of that, but I suspect my noise problem is "centered" much lower in frequency. I am going to use an HF loop.

> If you have a handheld am radio with internal ferrite rod antenna then you
> can "null out" the noise (antenna receive less from its ends) ...

I did that. The noise is so strong on the BC band that is simply overwhelms the receiver, and since the receiver has no attenuator, I can't reduce the signal low enough to find anything.

> Where both lines cross ... there is your source

Yes. Triangulation. I have already printed off a detailed map of the area, and have my compass and straight-edge.

> (same with using a yagi on 2m am)

Yes.

At one time when I was much younger, I owned a military DAG-1 DF receiver. Small, portable, tuned from BC to 18 MHz. Built in loop electronics, loop mounted on top of the case, compass installed in the loop. Wish I still had it.

Thanks to all for the advice.

I am now building a shielded loop so I can continue my investigation.

Did that too. It doesn't. Also, this particular furnace does NOT have a variable speed motor on it. From my reading, this is the thing that is causing major problems: the motor speed control.

> It's a wild shot but you never

No. Different company. Besides the Avista guy told me all about those remote-reading meters, tested those nearby and found nothing out of the ordinary. He DID say that there was a bank of those about 4 blocks away that seemed a bit noisy, but not excessively so.

Kenneth

Your loop does not have to be resonant ... so 1-2m of stiff wire ... connected direct to coax (or in other words a big pick-up loop) is all what is needed

No need to make a real magnet loop antenna (with coupling loop and capacitor) ... cause you only wanna receive ... and you do not want max gain but only directivity

31730. Dielectric Fillers for Coaxial Connections

Yahoo group: ham-antennas (2014)

From: <joel@...>
Topic: 31730 Message: 31730

Has anyone had any experience with a product called STUF, marketed by Cross Devices? It is a silica / Teflon filler product that purportedly prevents moisture infiltration into coaxial connection junctions. Living in an area of the country where there are wide swings in ambient temperature and long duration high humidity. Additional product information is available at www.crossdevices.com/cross_devices_002.htm http://www.crossdevices.com/cross_devices_002.htm . Any insight is sincerely appreciated for an upcoming feedline project! Thank you.

Hi Ken,

In a way you may have narrowed the noise source down to some degree. Ok, looking at the facts so far we have:

1) You did not have this noise until your neighbor got the new furnace.

2) The power company narrowed it down to the basement and gas line of your neighbor which appears to be the offending items. Let us assume that the guy is right based on what you said about his actions in the past.

3) The service tech which you know turned off the furnace and the power in the neighbors house and the noise persisted.

a. Did he turn off the breaker to the furnace or the whole house main breaker? The reason I ask is did they have to put in new thermostats for the new furnace? If they did they may not be on the same breaker and could be radiating the noise.

4) We are both old time tech's and we both learned that you need energy to create a signal. So if he did turn off the main breaker that leaves us with the question of galvanic energy creating the noise which could be a real bear to track down I personally do not believe it is galvanic in origin,

5) The next steps I would take.

a. You are making the loop antenna for the 890 to sniff the source.

b. Use a cheap transistorized portable radio and scan around the neighbors furnace to see if you can spot where the most noise is coming from.

c. Use a VTVM and check the case of the furnace to ground to see if you get any voltage readings. It should read zero if the furnace is grounded properly.

d. Check their service ground to be sure that is working properly also. A bad house ground could be a noise generator as well as a hazard to the elderly couple.

e. Check their main panel to see if they have a lightning arrestor in the panel. After a couple of hits they should be replaced because they will generate noise and are no longer protecting the house. They operate pretty much like the ones we use on our antennas and can go bad.

f. Using the cheap portable radio turn off the main breaker yourself to check the noise level. See if it goes away or reduces in level.

g. If the noise remains after you turn off the main house breaker then the source might be outside at the meter or the connections to the drop at the house. I know I ran into a problem at my own house where the ground connection to the pole feeding my house was loose and only my ground rod was working. This created noise.

6) Using the 890 did you scan through its entire receive spectrum to note what the frequencies are that the noise is on? I do not remember you posting where the noise level was that you were hearing it at. Also is the noise continuous? It's a long shot but this may tell you the fundamental frequency of the noise and the rest of it is harmonics. If you spot a fundamental frequency it could help you track down the noise source rather than a random noise.

Damn I really wish I lived closer to you. You know how old techs love a good challenge. BTW loved your boat anchor collection. You have some really awesome VLF receivers. I tend to collect boat anchors myself. Especially refurbishing them and getting them on the air. Nothing like the glow of a tube to warm the heart.lol. Again I hope some of these ideas help you.

Unfortunately, no. I have already asked for help, and there were none who
knows more than I do.

> I just
> had another thought. Check with your friend the service guy and ask him if
> the furnace controller has a back up battery connected to it so it doesn't
> lose programming in case of a power failure.

Did that too. It doesn't. Also, this particular furnace does NOT have a
variable speed motor on it. From my reading, this is the thing that is
causing
major problems: the motor speed control.

> It's a wild shot but you never
> know. When they put in the new furnace did the gas company change out the
> meter by chance?

No. Different company. Besides the Avista guy told me all about those
remote-reading meters, tested those nearby and found nothing out of the
ordinary. He DID say that there was a bank of those about 4 blocks away
that seemed a bit noisy, but not excessively so.

> A lot of newer meters now allow the companies to just drive
> a truck through the neighborhood and they record your usage remotely.

Yes, as I said, the Avista guy told me all about those, and tested all those

nearby.

Thank you, Mike. I am now building a loop to connect to the FT-890.

I'll keep the list informed of progress....or lack of it.

Hi,

I cannot help with that specific product but I normally use self-amalgamating tape. Wrapped tightly over and around connection. Has to be cut off, even after 10 years and connectors look as good and bright as new..

Cheers
Will

Sigi,
Is the loop directional in the same way at all frequencies if not
resonant?

Hi,

I am not sure why, but I find that photo of the PL-259, with the pile of "stuff" in it very disturbing... The thought of sealing it in for 10 or so years bothers me for some reason... Like the ZL fellow, I use the tape he described... It is called Rescue Tape at True Value Hardware stores... It works wonderfully well... I have had connectors 10 years old come out looking brand new... Seeing all of that "stuff" inside the connection would make me very worried after a few years... But I have zero experience with it either.

This could just be a case of going with what I know works...

My experience in the high sun/uv & salt that affects much of ZL is that aluminium and clear silicon don't go together. I used to smother A/e connections in the stuff but after a couple or three years it was crystalline and bonded to the metal. Turned to effectively glass. That is why I went to tape.

I certain;y wouldn't want to fill connectors with "stuff"" and hope it kept the water out.

What does it do to the impedance and velocity factor?

Cheers
Will

I'm still thinking about the connection between the start of the noise and the installation of the new furnace. New furnaces probably use digital thermostats powered by batteries installed in the thermostat. If the thermostat(s) were a noise source it would be unaffected by turning off house power, and the wiring between the furnace and the thermostat might make a good antenna for it. Just a thought on a tough problem - expect the unexpected.

Yes it is

1m wire used on 11m (many years ago) ...

The sensitivity is way lower ... but directivity is the magnetic component (if your loop is not that big to be self resonant)

And you WANT lower sensitivity for the hunting of such a noise source

Try it out ... if sensitivity is tooo low ... just use a bigger loop

When you come close to the noise then use smaller loop

Can be build IN SECONDS

I would just take a few feet of "house wire" and a short piece of coax to the rig

Cause it is just a quick and dirty thingy you do not need to make it resonant nor add a handle bar :-)

And ... when you come close to the noise source then maybe also on 2m or 70 cm you can receive that noise ... and then use a yagi and pin point the noise source ...

Some noise sources produce such a high noise level and are so wide banded that when you come close you can receive it without any antenna

... but ... first you have to know a rough area (what house/pole/transformer etc) ... and that should be an easy task if it is a permanent noise

If it is only on cold days then maybe a furnace (most times the variable speed motor) ... if only at night ... then maybe a street lamp ... etc..

So ... finding a noise source can be tricky or easy ... depends on what kind of noise, when and how often, ... what is "the sound of the noise" ...

Good luck in finding :-)

Sigi,

Thanks, I was under the impression that the directivity was related to
loop size! Think I will make a slew of loops, or one I can change...
My loops have always been resonant.

31744. Re: AW: [ham-antennas] Noise - source NOT identified.

Yahoo group: ham-antennas (2014)
Date: 2014-03-13 13:48:22 UTC
From: <wd4aon@...>
Topic: 31702 Message: 31744

OK, I think you might want to open your mind a little further and work on other potential sources of RFI. With the house AC mains OFF, what other sources of electricity are there?

Is there anything in the house that is battery operated? Battery backed up clock or something like that? Battery operated outdoor grill sparker? Wireless computer mouse/keyboard? Wireless indoor/outdoor thermometer? Security system? TV or fan remote controls? Anything solar operated/powered? Anything that might have a built-in rechargeable battery that stays on operated by the battery when AC power is lost?

How about the telephone lines - can there be some RFI leakage coming in there? Any cable TV line?

Have you checked for any other changes in the household that occurred at about the same time? Anything new or recently added?

What kind of noise is it - white noise, pink noise, a steady buzz, is it of variable noise level or modulation? Is it continuous or intermittent? If intermittent, regular cycling or irregular? If irregular, does the cycling match anything like weather, temperature, daylight, etc.?

NOTE: It may be useful for someone brighter than I to compile all the ideas that have been suggested in response to this problem as a sort of FAQ or checklist for others to use.

> My loops have always been resonant.

For receiving and/or for DFing, loop sizes greater than about 0.1 wavelength in "circumference" make the nulls LESS obvious or broader. I say "circumference" since loops don't have to be circular. Square works about as well.

For instance, a loop that is about 0.1 wavelength in circumference at 40 meters exhibits strong and deep nulls on 80 and 160, but broader nulls on 40, although they are still there.

And another factor I discovered the other day while searching for good loop designs: a multiturn loop will often exhibit lower RF "recovery" than a single or two-turn loop. In other words, a multiturn loop will be LESS sensitive than a single or two-turn loop of the same size.

This is, apparently, true for both shielded and unshielded loops.

Also, making the loop resonant is always good. Untuned loops can be useful, but they are usually far less sensitive than a tuned loop.

Hello, Chuck. Well, so far we have eliminated the next door neighbor's furnace completely, thermostats and all.

It turns out that the device the Avista man brought down here to check with is an acoustic device, and does not detect HF RF signals at all.

I am going back to him later this week to see if we can get some gear that will be more helpful.

In the meantime, I am resurrecting one of my "ancient" Stoddart NM-20B "Noise Meters". All of the Stoddart gear I have was specifically designed to find this type of noise. The type's modern name is RI/FI meter, or Radio Interference/Field Intensity meter.

The NM-20B (also the AN/PRM-1) tunes from 150 Khz through 25 MHz and has a BFO. It has three loops for it, a "small" one about 8.5" in diameter, a larger one (which not only do I not have, but there isn't even a photo of it in the manual), and two other devices, a small hand-held "loop" about 1" in diameter, and a device to allow the receiver input to be connected directly across an AC line.

And the manual is LOADED with excellent information on how to find noise.

The receiver has a really large meter for measuring microvolts/meter, and outputs for a 'scope and a chart recorder, in addition to headphones.

The build-quality is simply the most beautiful stuff I have ever seen.

Stoddart made such receivers to cover from 20 Hz through 18 GHz.

I am waiting from some parts from Mouser to complete the refurbishment of my NM-20B's power supply.

The, "...a hunting we will go..."

Thanks Ken,
I have a loop I use on 40, which is well less than .1 circumference,
and it has serious nulls, like 35 or so db! That made me happy.

I have not tested it on 80 yet, because I assumed the directionality was
unpredictable at non resonant frequencies.

Thank you for suggesting that.

Hello, Chuck. Well, so far we have eliminated the next door neighbor's
furnace completely, thermostats and all.

It turns out that the device the Avista man brought down here to check with is
an acoustic device, and does not detect HF RF signals at all.

I am going back to him later this week to see if we can get some gear that
will be more helpful.

In the meantime, I am resurrecting one of my "ancient" Stoddart NM-20B
"Noise Meters". All of the Stoddart gear I have was specifically designed to
find this type of noise. The type's modern name is RI/FI meter, or Radio
Interference/Field Intensity meter.

The NM-20B (also the AN/PRM-1) tunes from 150 Khz through 25 MHz and
has a BFO. It has three loops for it, a "small" one about 8.5" in diameter, a
larger one (which not only do I not have, but there isn't even a photo of it in
the manual), and two other devices, a small hand-held "loop" about 1" in
diameter, and a device to allow the receiver input to be connected directly
across an AC line.

And the manual is LOADED with excellent information on how to find noise.

The receiver has a really large meter for measuring microvolts/meter, and
outputs for a 'scope and a chart recorder, in addition to headphones.

The build-quality is simply the most beautiful stuff I have ever seen.

Stoddart made such receivers to cover from 20 Hz through 18 GHz.

I am waiting from some parts from Mouser to complete the refurbishment of
my NM-20B's power supply.

The, "...a hunting we will go..."

31756. Re: [ham-antennas] Loops and directivity

Yahoo group: ham-antennas (2014)
Date: 2014-03-13 22:53:47 UTC
From: Andy
Topic: 31702 Message: 31756

My understanding is that a loop's directivity is not affected by the use of an "antenna tuner" (i.e., a capacitor) to make it appear electrically "resonant" from the feedpoint. OTOH, a loop that is naturally resonant without an added cap is an electrically large loop, close to 1 wavelength in circumference. That loop's directivity will be totally different than that of a small loop.

As long as the circumference is smaller than about 0.1 wavelength, then size shouldn't affect directivity. Going to a smaller frequency means the size is even smaller compared to a wavelength. If it already was small enough to have good nulls, its nulls should be just as good at the lower freq. (maybe even better).

Tuning a loop to make it "resonant" mainly just changes how effectively it can transfer the energy into the receiver.

Andy

Correct. In fact, the Stoddart NM-10 "Noise Meter" I have here does just that and, in fact, parallels the loop's internal capacitor with external tuning caps so that it is resonant at whatever frequency you are tuned to. The loop itself (500 uH) with the internal 200 pfd capacitor is resonant at about 500 KHz, then the tuning system allows resonating the loop at the receiver frequencies, which cover from 14 through 250 KHz.

> OTOH, a loop that is naturally resonant without an added cap
> is an electrically large loop, close to 1 wavelength in circumference. That

Yes. It would be much more effective as a transmitting antenna, and most certainly would be almost useless for DFing.

For DFing at HF, especially over along distance, the Adcock array is excellent....unless one could afford a Wullenweber array (AN/FLR-9)...

> As long as the circumference is smaller than about 0.1 wavelength, then size

They normally ARE better, but at the lower frequency, the loop efficiency becomes less: i.e., the loop is less sensitive.

> Tuning a loop to make it "resonant" mainly just changes how effectively it can
> transfer the energy into the receiver.

Yes, but sometimes that can be quite significantly better.

Hello, Chuck. Well, so far we have eliminated the next door neighbor's
furnace completely, thermostats and all.

It turns out that the device the Avista man brought down here to check with
is
an acoustic device, and does not detect HF RF signals at all.

OMG Ken, it seems like nothing is working out correctly for you. I can't
believe he brought an acoustic detector instead of an RF one.

I am going back to him later this week to see if we can get some gear that
will be more helpful.

In the meantime, I am resurrecting one of my "ancient" Stoddart NM-20B
"Noise Meters". All of the Stoddart gear I have was specifically designed to

find this type of noise. The type's modern name is RI/FI meter, or Radio
Interference/Field Intensity meter.

The NM-20B (also the AN/PRM-1) tunes from 150 Khz through 25 MHz and
has a BFO. It has three loops for it, a "small" one about 8.5" in diameter,
a
larger one (which not only do I not have, but there isn't even a photo of it
in
the manual), and two other devices, a small hand-held "loop" about 1" in
diameter, and a device to allow the receiver input to be connected directly
across an AC line.

I think you are on the right track going this route.

And the manual is LOADED with excellent information on how to find noise.

The receiver has a really large meter for measuring microvolts/meter, and
outputs for a 'scope and a chart recorder, in addition to headphones.

The build-quality is simply the most beautiful stuff I have ever seen.

Stoddart made such receivers to cover from 20 Hz through 18 GHz.

I am waiting from some parts from Mouser to complete the refurbishment of my NM-20B's power supply.

The, "...a hunting we will go..."

I'm sure it is meant to locate power line noise coming from bad insulators and transformers. He must have thought the source of the problem would be wiring on the utility poles. That's what they use to find those offenders.

Hi,

He may have been following the guidelines set by his company... It may be that the Power company does not want to become involved in locating non power company sources... Once they rule out their own equipment, they are essentially out of the picture, unless they choose to be involved.

The power companies are under no obligation to help beyond, the "it's not our fault" stage of things. I mention this to be sure you are aware of this, which you probably are.

Whatever happened to banging on the poles with a sledgehammer at night, looking for sparks? (humor)

Loops and noise problems go together.

I have an 80m full wave horizontal loop terminated with an MFJ 4:1 Guanella (?) current BalUn driving RG8X. It is about 15' above ground. They are actually "resonant" at half the physical length, and all higher frequencies (within reason). The theoretical polarization is vertical. This is my SWL BCBDX antenna, for my bedside Lowe HF-150. It is virtually deaf to everything in the house except the microwave oven. It doesn't pick up the next door neighbors' light dimmers. Web Search for "sky loop"

31763. Feeding a collinear array

Yahoo group: ham-antennas (2014)
Date: 2014-03-15 12:31:57 UTC
From: Original Woodchuck
Topic: 31763 Message: 31763

HI,

A question or three...

The hypothesis: imagine a collinear array of two horizonatal dipoles. They have been trimmed and elevated so that they have (each) a feed point impedance of (surprise!) 50 ohms. Now we arrange to feed them, deciding that they should be fed in phase.

To do this, we connect 1/2 wavelength of 50 ohm coax to each mid-dipole feedpoint. Each of these 1/2 lambda phasing cables has, at its end, an impedance of 50 ohms. Why? Because the dipole has a Z of 50, and it is 50 ohm cable, and, regardless of its length, it is a line terminated in its characteristic impedance.

We then join these two phasing lines in a garden variety 50 ohm T-connector. The outlet of the T is connected to a 50 0hm coax to the transceiver, "of any length."

Question 1: The impedance seen at the outlet of the T connector is 25 Ohms, true? There are two 50 ohm loads in parallel, hence 25 Ohms. (This is a sanity check).

Question 2: Why not place a 1:2 transformer at the outlet of the T, or some other way of flattening the feedling from the T to the transceiver? Why induce a vswr of 2 you can avoid?

Question 3: The author (this is from the ARRL Antenna Compendium Vol 7) is adamant that these phasing cables be 1/2 wavelength long. Why? It seems to me that the phase angle between array elements will be 0 for any length provided that each cable has the same length. Other authors also get picky about this 1/2 lambda length, but they are talking of arrays that are phased at some other angle. Is there any reason for /this/ array, fed in phase, to have phasing cables that are exact multiples of 1/2 lambda? It seems more like witchcraft than science. Sure, if they are not in phase, then I might understand a load balancing problem. It would seem that to feed in phase, all that need be satisfied is symmetry.

From: Artek Manuals
Topic: 31763 Message: 31764

For starters even though the dipoles by themselves are 50 ohms ...once they are fed in phase (or out of phase as the case may be) The impedance of the two dipoles changes because of the coupling between the two dipoles. There are all kinds of graphs and equations for predicting this.

1/2 wave line is often used because in the case of a mismatch the measured impedance as seen at the end of the line (assuming loss-less coax) is exactly the same as the input impedance regardless of the mismatch. Other lengths will produce an output impedance that is different than the input (read the section in the ARRL Antenna book on matching stubs to get some insight)

None of which, I believe, apply for collinear dipoles. The case is "in phase". We want equal power in each dipole. We want symmetric patterns, etc etc.

Yes. We all know this. I hope. It is good to put it on the table, though.

> impedance that is different than the input (read the section in
> the ARRL Antenna book on matching stubs to get some insight)

Oh, I'm well aware of the feedline equation. My awareness tells me that the two phaselines have the same input Z (at the T), and the symmetry of the problem tells me that the two dipoles are indistinguishable. The feedline equation then informs me that the equations for each phaseline are the same, i.e. work the same transformation on each element.

> Dave
> NR1DX

Thanks!

How much do two antennas that are collinear couple? My instinct says "not so much." At least in free space, a dipole has a null there. (But I would argue that it doesn't matter if the dipoles were parallel, provided symmetry was maintained.) So suppose they *do* couple. There is symmetry in this problem, and it says that what A does to B, B does to A.

By "doesn't matter" I mean that dipoles A and B dissipate equal power, given equal phaseline lengths. So I guess the issue is, is that power the same if that equal length is not 1/2 lambda? Even if everything is uncoupled, the antenna array is not matched to its feedline, the array presenting 25 ohms (at the outlet of the T).

How does coupling make A and B *different*? If they're not different, then how can one end up with a current different from the other? How can impedances that are not matched -- but are the same mismatch for each antenna -- result in any difference at all between A and B?

Symmetry means that if we write a complete description of this array, with a subscript A for one element and B for the other, then we can interchange subscripts everywhere and the equations stay the same.

You see my problem?

I believe the answer has to do with power transfer in the general case, and I believe this particular author to possibly be wrong.

True enough in the case of collinear dipoles. Even then, spacing between the ends of the two collinear dipoles does change the impedance by about 25%...free space collinear dipoles with very close end spacing are more like 90 -100 ohms versus the theoretical 72 ohms., so two dipoles with minimal end spacing would be more like 90 ohms would then present 45 ohms at the output of the T so that would make sense to use a 1/2 wave in that application

I'm sorry to seem like a pest, but *why* does it make sense?
It can't change the phase angle. It would improve the match
at the T output, I agree. Is it all about power?

Trying to run NEC2 on this...very illuminating. Hmmmmm.

Thanks for your help, Dave!

Yes it is about power and match to the feed line....Your could feed it
all with open wire line as was done originally back in the tube days.

Or just use a longer dipole and one feed line :)

Best regards - Bry Carling

31770. AW: [ham-antennas] Feeding a collinear array

Yahoo group: ham-antennas (2014)
Date: 2014-03-15 17:31:54 UTC
From: siegfried jackstien
Topic: 31763 Message: 31770

What about usingt 3/4 wave of 75 ohms line to the t

Halfwave of 75 ohms does nothing to the impedance so the only thing that
does anything with the impedance is the left 1/4 wave of 75 ohms ... that
transforms the impedance of your dipoles to about 100 ohms at the t ..
parallel this and you have 50 ohms and can connect any length to the shack

(just as an idea how to avoid transformer)

That overall calculations does not include mutual coupling between the
dipoles (and so impedance changes of them)

thats all I did with my eme array odd multiples of 75 ohm cables long
enough to reach as needed then "TEED" together. works great!

Glenn,

Let's first ask why you would be using a tuner on 6 mtrs ?? Can you put up a resonant antenna for 6 mtrs ? If you are not using a resonant antenna, what type of feed line are you utilizing with the tuner ? Very few tuners are rated through 6 mtrs as they are rarely used up at the frequency.

Look forward to hearing from you.

You could check Palstar. The rating on 6 is probably considerably less.

I'm not a serious 6m guy but use my 80m loop and Palstar AT2K on 6.
For me 6 is not worth additional investment.

Dave,

Just curious what you are trying to accomplish. More gain with a single rope to hang both dipoles? Heading down the curtain array path?

I have a homemade rotor for my mast and antenna. I plan to rotate the entire mast plus antenna from the base of the mast support structure. I can can control turn direction for full CW or CCW 360 degrees but I want to add a compass direction sensor. I have seen inexpensive magnetic field I2C sensors but instead of re-inventing the wheel - does anyone manufacture an add-on type of device that I could use to give me compass direction?

31783. Way to graph the rise in impedance of a shorted 1/4 wave stub?

Yahoo group: ham-antennas (2014)
Date: 2014-03-21 16:19:13 UTC
From: Ray, W4BYG
Topic: 31783 Message: 31783

I wonder if anyone knows of, or how to, graph the impedance rise along a shorted 1/4 wave coaxial stub given the short ("0" Z) at the shorted end and the expected load impedance at the open end?

I have looked thru many references including League handbooks, Compendiums, Jasik and Kraus and others, as well as online and haven't found anything that seems applicable or helpful.

Any assistance would be appreciated.

Sounds like the telegrapher's equation.

```
* Zin = Z0 * (ZL + Z0 * tanh(gamma * l) / (Z0 + ZL * tanh(gamma * l)));
*
* where Zin = input impedance of line, ohms
* Z0 = characteristic impedance of line, ohms
* ZL = load impedance, ohms
* l = length of line, units consistent with gamma
* gamma = propagation constant = alpha + j*beta,
* where alpha = attenuation constant, Np/length
* beta = phase constant, radians/length
* beta is in fact the wave number, 2pi/lambda.
```

Looking at that, it may be that you have overdetermined the problem.
IOW, you have specified Zin (0), ZL, Z0 and l. (Note that the Z's
are complex, and tanh is the complex-valued function of a complex
argument.

That is exhausting this poor chemist's understanding of the problem.

The simple graphical way would be to use a Smith Chart.

But most people seem to shy away from Smith Charts. However, it tells you what you are looking for. If you want to go from there to a plot vs. frequency, you would need to read the values off the Smith Chart and plug them into a rectangular plot.

One could also use, say, LTspice (free) and simulate a shorted or open transmission line, and plot the impedance.

31788. Dumb Newbie Question on Rotor Installation Basics

Yahoo group: ham-antennas (2014)
Date: 2014-03-23 12:48:15 UTC
From: <jsternmd@...>
Topic: 31788 Message: 31788

Though licensed for many years I have always relied on wires and never been up close to a rotor or rotor controller. Finally installing a mast, rotor and hexbeam. I assume all rotors have some mechanical setpoint for a hard stop otherwise I can see lots of twisted coax wrapping around the mast if the rotor can do more than 360 degree rotations in one direction. Are all rotors set for 360 degrees or is there some overlap so you can go a bit more either fully CW or CCW? If they can only rotate a full 360 then am I correct that the setpoint should be placed on a heading about 90 degrees off from the headings most likely to be used a lot? For example, I live in CT and if I install the rotor with the hard setpoint due West, if I want to go from NW to SW I would need to turn the rotor 270 degrees not 90 degrees. So if due West was my expected most frequent heading I should probably install the rotor with the setpoint either due South or due North? I guess I am overthinking this but would appreciate some basic advice.

1) Most all commercial rotators are set for 360 with "limit switches" inside the rotor head
2) Most rotators have compass style set dials (N, S, E W or degrees 0-360, or both) and are North (or 0deg) Centered

My personal preference, been using a rotor since the early 70's is to have the "Dead Stop" due north.

Being here in Illinois and Wisconsin, the daily propagation would be similar to yours. Yes there is propagation directly to the north. But as a percentage of time,, not a whole lot where it would be flipping back and forth between say 20 degrees and 340 degrees. It is going to be either east of north or west of north. but rarely both for hours.

At sun up the bands are open towards the east like Europe and such so you start off at 45 degrees or so.

As the day progresses along the propagation sweeps clockwise around the globe. Next into Africa, then South America and finally late afternoon / evening into the Pacific and Japan areas.

Here is a Nice Video I made a while ago showing how the propagation moves like this during a day. A screen grab was made every ten minutes then a video was made showing each ten minute step separated by 1 second, it neatly shows this "Rotation"

Most rotators are set to north ... but some can be converted to dead-point at south ... (mostly sold in vk, zl ... south africa hi hi)

Some better rotors have a small overlap at that dead spot ... 450 degrees ... so you have 45 degrees in both directions as overlap

Remember your hexbeam is not the same as you would have a 20 over 20 el on 2m (or a bigger eme array) ...

So ... even without that overlap you should be fine

Hello Before you install your rotor you should hook it up and check out its operation to make sure it works and works properly that is it fully rotates and smoothly indicates the rotor direction. It is a lot of trouble to install something like this then find out it only partially works. If this is a old rotor that has not been used in a good while or used and not serviced you might even consider taking it apart and greasing and checking for wear but you would want to have the machanical ability to do this. There are several write ups with pictures on the web about how to this for most rotor models.
I would recommend you set the rotor at mid point which should be north unless you have a rotor as mentioned that is set on south as mid point. Then when you install it and your beam set it pointing due north and you will have 180 degree rotation in each direction. Besure and tighten the mounting hardware good to prevent rotating in the wind.
I hope that helps some and wish you luck with your antenna you will find that a directional beam like that makes a world of difference in what you can hear and work. I know it did for me when I put my first beam up many years ago.

31796. M2 6M7JHV broken feed idea

Yahoo group: ham-antennas (2014)
Date: 2014-03-23 19:55:47 UTC
From: Keith Heimbold
Topic: 31796 Message: 31796

All -

I am on a DXpedition to the inlaws in San Antonio and my feed point T match is broken on my 6M7JHV.

Anyone have any ideas of an alternative feed I can do with this antenna that would make the antenna work. I have a 1:1 unun and some extra coax and was thinking of direct feeding it somehow. Maybe insulating the elements from the boom and seeing what happens. Not sure what to do. Desperate in Castroville.

Thanks & 73,

I am amazed that the Yaesu rotor has not much more than an honorable mention in this thread, It was mentioned that some rotors turn 450 degrees or have an overlap of 90degrees. Actually the Yaesu rotors do that , they are also capable of having the field reversed . I suppose this just shows to what extent HyGain had dominated the market for years, Chuck Wq5B

I also have a 4:1 balun I could use from an OCF dipole. Not much else here.

Bummed in San Antonio and there is a major 6m opening to VP8 going on right now. Super bummed.

Do you have a VSWR meter? Or a DIP meter? A t-match isn't that complicated. Use math to approximate shunt position, meter to fine tune. There is probably a compromise that works acceptably on all 3 bands. Worst case, change it to a Delta match and work it unbalanced. Just a few WAGS, 73 de dave/kd6il

Here is another good point from Ron KA4INM - sent me this email says he can not post to group for some reason but hopes to get that working soon. Don't forget to tell then to make the final test on the ground with
all of the rotor control cable that will be used before hoisting the
rotor. Sometimes it is tested with a short cable and connected with 150
or 200 feet of too thin of wire to operate the motor.

We are all pulling for you Jerry 73 good luck.

31804. RE: [ham-antennas] Dumb Newbie Question on Rotor Installation Basics

Yahoo group: ham-antennas (2014)
Date: 2014-03-25 19:50:00 UTC
From: Scott Myers
Topic: 31788 Message: 31804

Jerry,

There is no way you can over-think a rotator choice. Give it plenty of thought and discussion with others. The questions you asked just started scratching the surface.

Rotators fall into numerous categories and sub-categories. You have to choose braked or non-braked. Drives types are spur/ring-gear, worm gear and planetary. Then there is construction type; clam-shell bearing VS shaft bearing. And finally the drive motor type; AC or DC motor. (There may be other things, but those are the things I can think of off the top of my head.) Not all rotators have "end of rotation" limit switches, but most do. Oddly, some of the more heavy duty rotators do not have limit switches, but rely on the controller software to know when a rotation error occurs, which works well too. The best controllers have software that "watches" things to keep the potential for cable wrap at a minimum. But no rotator is completely immune to the dreaded cable wrap potential, but some are better than others and a really good controller greatly minimizes the potential.

The lighter duty types are the clam shell/spur gear types are the cheapest and the most ubiquitous. The upper housing rotates with this type design and the mast clamp is part of the housing. Think Hy-Gain "HAM" type rotators. I think the Tailtwister was the largest of this type. These all use wedge brakes. A smaller clam-shell is the largest you would need with a Hexbeam. If this type has a "Weakness" it is the wedge brake which can require rocking to release when it gets under heavy torque from wind. Maybe this won't happen with a Hexbeam due to equal wind loading nature of a Hexbeam, but I don't know.

Planetary drives fall into the medium-heavy and heavy duty range. The medium heavy starts at the some of the Yaesu models with the "Prop Pitch" being the king of the hill in the heavy duty (and price) department. Planetary boxes come in both shaft and clamshell designs.

Worm gear are also in the medium-heavy and heavy duty designs, with Prosistel and Orion coming to mind, although there quite a few more. These are usually shaft bearing design rotators, but a few are clamshell.

Worm gear and planetary types typically do not use brakes as their natural high gear down ratio effectively locks them in place. They will turn easily even when under heavy wind torque from an unbalanced wind load. There are some lower ratio types that do use brakes, so this is not a 100% rule, but is usually the case.

Lighter duty/older designs (clam-shell) tend to have the AC motors while the never designs and heavy duty units tend to have DC motors.

As far as the controllers go, if you just want (or can only afford at this time) manual control, stick with whatever comes with the rotator. If you want computer interface, added functionality and additional safety from cable wrap, it would be my suggestion to move up to a Green Heron controller as they will support ANY rotator that I know of through jumper changes inside the controller. (Except the Prop pitch, which requires a special Green Heron, which is WAY WAY beyond your needs.) And of course, the Green Heron will watch for

problems in the feedback to keep cable wrap from occurring. And their phone support is top notch as well. But they come at a healthy price. A Green Heron can be added at any time when your wallet will bear it. It's not the only choice, but it's about the best IMO.

As someone else mentioned, pay careful attention to your cable run length and voltage drop for the current required of your rotator's motor. I've seen more than one ham bitten by this unfortunate oversight.

Finally, you also have to consider whether you want to mount the antenna directly to the rotator with the rotator at the top of the tower or use a thrust bearing and a mast pipe, which is another entire conversation. I'd never advise the mount directly to the rotator and would only advise the thrust bearing myself.

That's my quick and dirty comments on rotators and controllers. There is a lot more to it than that, but it requires study to know the differences in rotators and why you would want one over the other. There is no "perfect" rotator, but the better they are, the higher the price.

Someone mentioned using a used rotator and making sure it is greased. In my opinion, if I bought a used rotator, I would not put it into service unless it was completely rebuilt before I used it; new bearings, switches, potentiometer and perhaps motor and gears. The reasons should be obvious, but everyone is entitled to their own opinion on this. Just remember that it doesn't get much worse than having to pull down a rotator from under an antenna. And it won't happen in the summer either.

Subject: [ham-antennas] Dumb Newbie Question on Rotor Installation Basics

Though licensed for many years I have always relied on wires and never been up close to a rotor or rotor controller. Finally installing a mast, rotor and hexbeam. I assume all rotors have some mechanical setpoint for a hard stop otherwise I can see lots of twisted coax wrapping around the mast if the rotor can do more than 360 degree rotations in one direction. Are all rotors set for 360 degrees or is there some overlap so you can go a bit more either fully CW or CCW? If they can only rotate a full 360 then am I correct that the setpoint should be placed on a heading about 90 degrees off from the headings most likely to be used a lot? For example, I live in CT and if I install the rotor with the hard setpoint due West, if I want to go from NW to SW I would need to turn the rotor 270 degrees not 90 degrees. So if due West was my expected most frequent heading I should probably install the rotor with the setpoint either due South or due North? I guess I am overthinking this but would appreciate some basic advice.

Hi jerry,

There is a lot involved with rotators. Lots come into play such as cost, worm drive, tilt for moon bounce etc. I have a hexbeam and in use a yaesu g-400a. This does the job fine and comes with controller and plugs all you need is the cable. Around 275$ from gigaparts.

I have a completely unused and complete prop-pitch motor here.

What sorts of controllers would the group recommend for this thing?

It LOOKS like it would be capable of rotating my house.

It also looks and feels as though it would need a crane to install it: it is heavy.

Recommendations?

Personally I would use the K3NG Arduino-based controller. It allows boyh Yaesu and Easycom protocols and will give even Radioshack/Channelmaster rotators serial control. You can find more info on the 'radioartisan' Yahoo group.

If you don't want to "roll your own", then a Green Heron RT-21pp is the way to go, but it's not cheap at $700. But then again, nothing about putting a prop pitch into service is cheap. The RT-21pp is easily interfaced to any computer or operates manually. The biggest problem with the Prop Pitch starts with the 24 VDC requirement and its near 8 amp inrush under acceleration and 5 amp nominal. This requires some large wire to minimize voltage drop. Now if you don't have a large antenna array and can live with less torque, then you can put in smaller wire, but only to a point. The longer the run, the larger the wire gauge needed. If you get far enough away from the controller (about 300'), you have to use a remote power unit to be practical, making the controller cost twice as much.

Bottom line: You have to really need a prop pitch to spend the money to put it into service.

There was a recent thread on the rafdioartisan group regarding a prop pitch motor. Yes, you would have to 'roll your own but it sure beats the $700 of the other choices.

31813. RE: [ham-antennas] Questions on Rotors

Yahoo group: ham-antennas (2014)
Date: 2014-03-26 16:29:47 UTC
From: Scott Myers
Topic: 31788 Message: 31813

You are right Geoff. The Green Heron is a pricey controller and saving money is always welcome, since everything else associated with a prop pitch is pricey. But does saving $700 truly beat the Green Heron in a prop pitch installation? It depends upon one's risk assessment to the total size of the investment. Let's talk about that, as most hams haven't been exposed to a prop pitch install. It's like no other.

If you already have a prop pitch and are not putting a high dollar array atop it, then it makes sense to start cutting costs and use something homebrew on the controller. This may be Ken W7EKB's case. If you are installing the prop pitch to handle a large array (as the usually case), then cheapening the controller cost makes much less sense. It's also important to note that if you are considering installing one and have never dealt with one, you may be in for some surprises. The prop pitch is an interesting and unique rotator with unique requirements and unless you've went through the motions of installing one, you don't know how unique it is.

When are prop pitches normally installed? What makes them so special? Why would you want one? Most hams have heard of them or even seen them and know they are sort of the "Holy Grail" of rotators. Their HUGE gear reduction (either 7,000:1 or 9,500:1) and the fact they were built for military plane propeller pitch control (hence the name), that's what. They are true triple-stage planetary gear drives and have stupid high torque capability that puts their safety margin so high that they yawn at turning a large array. But they do turn slower than most other rotators due to the high gear ratio. An interesting fact is that if you adjust for the time value of money for when they quit making the prop pitch in the mid 1950's, if they still made it now the SMALL unit would cost about $28,000 today. That gives you an idea of the kind of build quality and capability it has, as there was no corner cutting in its design like a normal rotator. It is a serious piece of hardware, but has serious install requirements as well.

Specs on prop pitch rotators from K7NV's site.

http://k7nv.com/notebook/ppinfo/

Most prop pitch installations are not cost cutting adventures as everything about it and around it is very expensive for the average ham. Even if you already own the prop pitch, it takes a fair amount of money to get it installed. You really have to truly need one for installing one to make sense, as it is in a completely different league than even a Prosistel PST-110D. But if you can get it installed, it will outlast you most likely and you will never have to worry about it.

The normal situation for installing a prop pitch is usually a high dollar installation to begin with and not just for a typical tribander. The small

prop pitch will fit in smaller towers like a crank up. (The smallest version of a prop pitch is larger than a Tailtwister, so it won't fit in compact crank-ups.) The medium size won't fit in anything less than Rohn 45, so you are already into some pretty high dollar tower. Even then you have to either cut out a cross brace or drop it in from the top, as it is physically long with the big motor on the bottom. And as Ken said it is HEAVY! When I took delivery of the medium sized one from K7NV I was shocked at the weight when I tried to pick up the big tube it came in, as I hadn't considered how much it weighed. Packed, it weighed about 80 lb. Just the heavy mounting plate made to take the appropriate vertical loading and a heavy duty top bearing plate for the appropriate sized thrust bearing will set you back $500, not including the thrust bearing! If you add an intermediate plate, even more money is needed. It sure ain't no Ham IV. hi hi

Usually some pretty big expensive antenna arrays are going atop prop pitch rotators on big towers with large mast pipes. There is so much money wrapped up in such a system that a $700 controller gets lost in the noise. The other issue is that when you've spent that much time, money and effort to install a large array and a pricey prop pitch, you want a lot of safety and dependability in the controller. The radioartisan solution is probably just fine, but most hams installing a new $3,000+ rotator (when rebuilt) with presumably $5000-$8000 worth of antenna sitting atop it, and all the other pricey items are usually not going to install a homebrew controller because it's not that "kind" of installation. The owners of such systems usually want a proven safe design commercially made controller to protect the tower and system. Not always, but this is typical with a prop pitch installation.

I'm rebuilding the top of our 135' tower at our club right now and putting in the medium prop pitch. We are rebuilding an original SteppIR MonstIR, replacing the top section of Rohn 45G, mounting plate, intermediate plate, top plate, bearings, mast pipe, replacing the M2 2M beam, and installing new hard lines and control cables. This system was in service for about 7 years, but it had mechanical problems due to too small a rotator (PST71D), torque wind-up of the original mast pipe and 2 worn out thrust bearings. We have a lot of people that use this system, so we need all the safeguards we can get, so we went with the Green Heron. But in a home shack with just one ham using it who won't take unnecessary risks anyway, a homebrew controller may be perfectly acceptable.

The one surprise cost I hadn't considered with doing an install of a prop pitch with a 280' wire run was voltage drop and wire gauge. A prop pitch has a high amperage requirement compared to other rotators, hence the need for a special controller. The minimum wire we could go with was 10 gauge, which causes a 10% voltage drop at nominal current draw of 5 amps. At the peak amps of 8, it hits 17%, but I expect that we will never see that because we will keep the ramp rate pretty low. Jumping up to 8 gauge nearly triples the wire cost and does get use down to 10% drop at 8 amp peak current draw, but at nominal current draw its only a 3-4% difference, which isn't enough in speed/torque to worry about. A prop pitch requires 3

parallel runs of the heavy gauge wire and 2 conductors of small size for the feedback.

There was a recent thread on the rafdioartisan group regarding a prop pitch motor. Yes, you would have to 'roll your own but it sure beats the $700 of the other choices.

On Mar 25, 2014 6:45 PM, "Scott Myers" <ac8de@...> wrote:

If you don't want to "roll your own", then a Green Heron RT-21pp is the way to go, but it's not cheap at $700. But then again, nothing about putting a prop pitch into service is cheap. The RT-21pp is easily interfaced to any computer or operates manually. The biggest problem with the Prop Pitch starts with the 24 VDC requirement and its near 8 amp inrush under acceleration and 5 amp nominal. This requires some large wire to minimize voltage drop. Now if you don't have a large antenna array and can live with less torque, then you can put in smaller wire, but only to a point. The longer the run, the larger the wire gauge needed. If you get far enough away from the controller (about 300'), you have to use a remote power unit to be practical, making the controller cost twice as much.

Bottom line: You have to really need a prop pitch to spend the money to put it into service.

I have a completely unused and complete prop-pitch motor here.

What sorts of controllers would the group recommend for this thing?

It LOOKS like it would be capable of rotating my house.

It also looks and feels as though it would need a crane to install it: it is heavy.

Recommendations?

Nahhh ..the Armstrong Rotators use a Pipe Wrench to turn the mast :-)

One thing to remember with rope pulley driven systems is that the sun
will rot the rope so think in terms of making the rope easy to replace
once a year

One could also use "aircraft" cable in the smallest thickness such that it would thread and roll easily through pullies. Even a pretty thin cable would be stronger than Dacron. Of course, more expensive, too.

I once had an antenna for TV outside my front door mounted on a Tulip Tree (Tulip Poplar, Yellow Poplar, *Liriodendron tulipifera*) that I would go out and twist around when the XYL changed channels. Have used the same sort of thing with 2 meters. A rope with several turns around the mast (tree, pole, whatever) and pinned to the pole in the middle of the turns, and the two ends of the rope fed through into the shack should work fine. Might even work for lighter HF antennas.

Armstrong Method! I like that!

The short answer is the butternut will be better for DX (low angle stuff) on 20-10M and the 43' Will be slightly better for DX on 80-40-& 30. For short hop stuff the results will be allover the map on each antenna

Why do you need to raise the B-Nut another 10'? you will unlikely get much if any performance improvement

Look in thee group archives for the last couple of years to see a more in depth discussion on the pros and cons pf the 43' vertical

31829. Mobile Antenna Tuning Issue

Yahoo group: ham-antennas (2014)
Date: 2014-03-30 05:12:41 UTC
From: <etsu1972@...>
Topic: 31829 Message: 31829

I have used a Little tarheel II on one of my cars for the last 5 years with great success mobile. Recently I decided that I would like to put a mobile rig in my 1989 Chevy S-10 truck but on the cheap. I found my old Hustler whips from many years ago and decided to use them on 75 and 40 meters.I bought one of the Hustler mounts for RV's since it was a strong mount.

I tried to tune the antennas in the garage first. I attached the 75 meter resonator to the lower end of the antenna shaft and attached the shaft to the 3/8 mount. I then sat the mount on the floor of the garage and hooked up the coax to my MFJ antenna analyzer. To my amazement the 75 meter antenna and the 40 meter antenna both resonated well below the 75 and 40 meter bands. Like 2.2 mhz and 5.1 mhz! No amount of adjusting the whips wound bring either antenna into the ham bands. So I tried a firestick mount and put it on the garage floor and sat the antennas up vertically as before and got the same resonance results.

However, when I placed both antennas into a magnet (3) mount on the floor of the garage both antennas easily resonated within the phone segments of 75 and 40 meters. I'm stumped as I was planning on using the rv type hustler mount. My last choice was to use the magnet mount. Note that I haven't placed any of these on my truck yet. What would cause this? Thank you, Greg, K4PVA.

The antenna needs a ground plane which is not provided by the garage floor. Put the mount on a vehicle before testing.

In minnesota, whre I live, it is common in most any poured concrete slab
to submerge a mat of wire for strength of the slab, In both garages, driveways,
and sidewalks. I'm sure that that's probably what retuned the antenna to
your unexpected frequencies.

I agree Mount the antenna or Mag mount and back it outside the garage to tune it. You may need to add a ground strap, What are you tuning it with ? An antenna analyzer? a Bird what meter? an inline SWR meter?

Tune it in the application not on the bench or the floor.

What am I saying I should listen to my own advise I do it also.

Thanks everyone for your suggestions. I will try to get the antenna mounted on my truck this week. I use a MFJ-258B antenna analyzer for tuning. Did not know about problems with concrete in the garage. I live in the Northwest and it was raining heavily for the last 2 days. That's why I way trying to do some tuning in the garage.

what is the best mag mount antenna? i know diamond has a couple of mag mounts that you can screw an antenna onto but i am looking for the highest gain and longest antenna that will work well with a crossband repeater. it will used on a non-moving vehicle's roof.

No such thing as a "best" mag mount....
Gotta stick and not scratch paint! I like my Larsen, but have used many others. If it moves @ hiway speed, I give it away.

I can think of one big reason...CC&R covenants! No antennas allowed, But....If attached to a vehicle, not much they can do about it. I know a number of people who do this, for everything from local repeater chit chat, to portable towers, mounted on trailers with good sized beams! I love that one..the community busy-bodies convinced the homeowner's board to fine him..when he refused, they sued. Guess who lost, and had to pay all kinds of penalties and legal fees for filing a frivolous, and baseless action?!! I just love that one.....he then mounted a remotely actuated, telescoping tower on the trailer....it goes up about 45 feet and another 10 with the mast. Nothing the homeowner's association can do...The only rule they have is if a trailer, it must be behind a 10' fence so as to hide the trailer...which it is...nothing about seeing what is *ON* the trailer.

More than one way to skin the cat!

From: Andy
Topic: 31839 Message: 31847

Don't mind me ... but I hate questions of the nature of "which is the best xxxxx". There are some very good ones of almost anything you name, and the differences between them may be minuscule or nonexistent.

It's also not clear if you were asking about just a mag mount, or about the antenna (the whole shebang).

If you want truly the best, it's probably advisable NOT to use a mag mount, but get a real mount that is cut into the roof and in physical contact with it. There is some compromise, small or not, when your signal needs to capacitively couple through a couple of layers to roof metal. Me, I have had excellent results with magmount antennae, but I know there's a chance I might be losing a fraction of a dB by doing so. That's OK with me.

Where is that crossband repeater you mentioned? Is it in the vehicle? And the vehicle itself is a mobile command post or portable repeater of some sort? (Either of those would be a good reason for having it on a non-moving vehicle.)

If it is a crossband repeater that you plan on hooking up to this roof-mounted antenna, it probably makes a difference.

Andy

Best one that i used and still have is the diamond nr770hb (n mount) but it is also available with uhf mount as nr770ha ...

Built like a tank with fold over mount

And it is a so called "radial-less" antenna

On 2m it is a halfwave and on 70cm it is 2 times 5/8 wave ...

It is on both bands "endfed high impedance" ... and it does work even with no roof below it at all (also used it in the hotel at the window with good results)

...

There is an old youtube vid from down under that shows how to make an easy 5/8 wave 2m whip with coax braid a small 11 turn base coil and shrink tube over a length of FG, made one a while ago with the top section of a 10m/CB 3 section FG antenna and it worked much better than my little 1/4wave mag mount, it hit repeaters that I had never managed before.

For my money, the Comet 2x6 is the way to go. It shows some of the best gains and still has good bandwidth.

My dislikes are that it has no shock spring and you are stuck with a fold-over joint at the base.

(Think of it this way... you're pulling into a low overhead parking garage, several impatient vehicles are behind you and it's raining.) NO FUN at all!

However, in a static situation you could do much worse.

Nope, I mean only the NMO receiver mag base that Larsen makes...would handle any NMO mounting antenna. Sorry if I misled you. I saw the question as asking about a mag mount only, not a particular antenna. The comments I made about how I select mine is only to the magnetic holding power of the base and its inability to screw up the finish on the ferrous surface to which it is "stuck" to.

Only if it is an NMO mag mount.....

I picked up a mag mount at a swap meet that has an 8" base and is NMO....It ***DOESN'T*** slide in the wind...I did cut a piece of fuzzy cloth and glued it to the base....still won't slide. Have no clue who the manufacturer is. I had a good SWR with it and that was what is important. (Had to go this route as the wife wouldn't let me cut a hole in the roof of her new car. Oh well!

Not exactly... The mag mount would have to have an NMO mount as well. Some mag mounts have SO-239 connectors.

Now that is a perfect reason to put an antenna on a non moving vehicle. It will work great. Any old mag mount will work if that is what you want.

You will get different results with the mag mount also so decide what you want to do.

I would advise against the mag mount if other options are available. I had RFI with a 3 mag and hustler triple tree with short mast 10,17,20. It was cured with a big snap on ferrite and 3 turns thru it.
Also with old/bad paint, paint will disappear under the magnet.

40 & 75 can be a little tricky sometimes.
You may end up needing some capacitance or inductance between the mast and ground to get close to 50 ohms, that's not uncommon. Maybe you'll luck out and not need it.

I just put the Hustler 20 back on my pickup to do mobile again using the short mast. I assume the short mast is less efficient but worked well before at a different mounting position which was top of cab. Rear bed rail now.

Hi..

At HF frequencies, and up to 6m, a physical bond of the ground side of antenna mount is probably necessary to get efficient operations. Normally this is done by drilling a mounting hole in the roof or bumper, or using a trunk lip mount and a "ground screw" that breaks the paint and gives metal contact. With a trunk mount you have to use copper braid to ground the trunk lid to the car's body; trunk hinges make for a lousy rf return path.

At VHF and UHF frequencies we can get away with using the capacitance between the mag mount and the body of the vehicle. Consider a 3 inch diameter mounting magnet with a layer of polyethylene covering it to protect the paint. Polyethylene has a dielectric constant of about 2.3 and the area of the magnet is about 7 square inches; using .005 inches as spacing between magnet and roof, the combination will form a capcitor of about 700pf. At 146 mhz, the reactance will be about 1.5 ohms, which would make a pretty low "resistor" for return currents. Larger magnet bases would of course have more capacitance, giving less reactance, and result in slightly more efficiency.

In short, with a good vhf/uhf mag mount, we can get away without drilling holes in our vehicles.

OK FOLKS:

Here are the rules of the reflector : HAM-ANTENNAS
This file will be sent once a month automatically to remind all users.

1. Name calling (race, religion, politics, gender, etc.), is prohibited.
2. Telling someone they are ignorant (in any way, shape, or form), is prohibited.
3. Denigrating other races or minorities, or expressing POLITICAL VIEWS will earn you moderation or banning.
4. If you do it privately it is a private dispute. When/if it spills over onto the reflector, you will be moderated or banned.
5. Even coming close to these boundaries is to be avoided.
6. Banning/moderation will be used, with NO notification to the transgressor.
7. Civil chatter and Civil wordage is THE rule.
8. IF the Moderators are offended, then penalties will be applied.
9. There are two Moderators, EITHER can ban/moderate you.
10. Moderators ARE the final arbitrator of disputes, we hate bickering!
11. USE Private or Direct Emails to address your concerns to the Moderators, because public postings may likely result in penalties as above. !!!!
12. Use common sense. If you would be hurt or upset if you received what you are about to send, and you are intentionally meaning to do that, DON'T DO IT!

13. We ALL would like to enjoy discussion about HAM-ANTENNAS, nothing more.

ham-antennasVideo recorded on 2nd April 2014 8:57 AM IST timings..in INDIA
i was going through the 10m band on FT-817ND qrp transceiver,
Recently placed an indoor end-fed random wire antenna for listening and
While surfing through the band this particular signal was received, the signal was extremely

strong about S59+++ and it had a large bandwidth about 10MHZ,also it could be received on all the

modes -- digital,LSB,USB,AM,CW....the signal was strongest on AM, so i believe it had to be an AM

broadcast ,i have no idea what this signal was could be a beacon or as a fellow ham told me it

could also be a long wave radar signal, but in ham radio frequency...frequency -- 28.845MHZ
Kindly go through the video and let me know if the signal can be recognized ..

today on 3rd april ,i had uploaded this video on facebook,even 2 different ham radio operators

confirmed that even they can hear it , DARYL LAMBLE from south africa just confirm it that even he

can hear it with 59+++ signal strength in AFRICA

Lots of mysterious signals out there. Does not sound like radar; see "Russian Woodpecker" on Wikipedia. Could be malicious interference, Sounded like some sort of modem signal. Be nice if somebody could do a direction finder on it. Triangulate it, and you know its location within a few miles.

I get this nearly every day here in Perth on 28 mhz from around 0400 to maybe 1200 utc [12 noon to 8pm perth time]
My beam heading is middle east when it is strongest up to s9 plus
It seems to from the middle east area and i read somewhere that it might be from EP iran. [not proven]
Some of us VKs call it the "fog horn"
It wipes out 10 metre ham signals.
May be some type of multi channel military radar or similar.
cheers from Perth

At 1315 utc from the Atlanta area it's strongest at about 30-45 degrees on a
5 el Yagi. I can hear it from 28.700 to 29.000 Mhz, weak at both ends of
that range and peaking at S7 near the middle.

31890. Antenna book

Yahoo group: ham-antennas (2014)
Date: 2014-04-04 19:32:39 UTC
From: James "Jim" M. Geidl
Topic: 31890 Message: 31890

I'm sure this is some kind of heresy but I just have terrible time understanding the ARRL Antenna Book. Can you guys suggest something different that I can read that will help me understand antennas? I know that I am supposed to have a complete understanding of the subject to have a General Class license but that just ain't the case.

Thanks,

Jim, K6JMG

Hi Jim,

I have most of the antenna books and every once in a while I turn the :The HF Antennas for all locations by Les Moxon G6XN. Published by the RSGB. Very practice and straight forward and, as you probably know, Les thinks out of the box. A good thing.

It is available from most amateur supply stores,

Cheers,

Mel, K6KBE

Hi Jim,

I have most of the antenna books and every once in a while I turn the :The HF Antennas for all locations by Les Moxon G6XN. Published by the RSGB. Very practice and straight forward and, as you probably know, Les thinks out of the box. A good thing.

It is available from most amateur supply stores,

Cheers,

Mel, K6KBE

I think the foundation for any HAM anywhere is found in the ARRL
handbook, and not necessarily the latest, but any written after about 1990.
Another learning aid is simply other HAMs, ask questions on the air,
on E-mail reflectors and join the nearest all service (not just a
repeater) HAM club. One that still gives tests and has code classes.
You won't learn anything on your first visit, but after a while a
subject will come up and you will interject a question and some kind
chap (or gal) will take the time to explain it to you and when you get
home, somethings in the ARRL handbook will make a lot more sense.
Luck helps but persistence always works in the end.

Jim, the ARRL antenna book can be a little heavy reading at times. I have no electrical background but I like to build things. Once I make something I don’t forget it. Start with a simple dipole, then a 2M vertical, different wire antennas are simple, a few scrap parts and you can put together a gama matched 2M beam. I made all of these before I even bought a analyzer. I build most of my antennas and baluns. Hands on helps me more. Just do a Google search on KD0ZZ and you will see several of my hits and misses in Photobucket. My 5 band dipole was a great hit, the 5 band vertical a complete miss.

After they determine that the book in question is not in the
readily-available collection, usually in the county or state union index,
the post to a system that is nationwide. Usually within a day or two,
they will know if the item is available, and whether it is currently
checked out to a borrower. If it is checked out, you'll have a wait, just
like in your local library.

Jim,

I just did a search on my local library web site using a tool they have called "Power Library" that lets me check all the libraries in Pennsylvania. That includes community and university libraries, so I get a list that includes simple books as well as engineering texts.

In the "consumer" class, check for books by Edward Noll and by Orr.

For heavy reading, try "Radio Engineering" by Frederick Emmons Termon (former provost of Stanford) and "Antennas" by John D. Kraus, W8JK of Ohio State University. John built the famous W8JK array and the "Kittoon". The Kittoon was a blimp-like antenna support for a vertical that stayed up like a kit in strong wind, and up like a balloon in no wind.

Although the math in both books is beyond me, some of the diagrams and bits and pieces of information are quite useful. For example, in one of these two books, there is a nice drawing of the patterns to be had from an array of two vertical antennas spaced at various distances and fed with different delays. Various lobed patterns, and even a cardioid pattern, useful for eliminating interference and great for direction finding are shown.

I also have on my own bookshelf Army tech manual TM 11-666 titled Antennas and Radio Propagation. It's old, but physics is the same today as in 1953. We just understand more today.

Good luck in your dig for knowledge.

From: James M. Geidl
Topic: 31890 Message: 31912

Rich,

what happens to a fan dipole like you have if the individual wires are very very close to one another? I have a role of 8 conduction flat wire that I have been thinking about cutting individual wire are ever increasing lengths starting at about 10m but not fan them out.

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

Subject: RE: [ham-antennas] Antenna book

Jim, the ARRL antenna book can be a little heavy reading at times. I have no electrical background but I like to build things. Once I make something I don't forget it. Start with a simple dipole, then a 2M vertical, different wire antennas are simple, a few scrap parts and you can put together a gama matched 2M beam. I made all of these before I even bought a analyzer. I build most of my antennas and baluns. Hands on helps me more. Just do a Google search on KD0ZZ and you will see several of my hits and misses in Photobucket. My 5 band dipole was a great hit, the 5 band vertical a complete miss.

Rich , kd0zz

Sent: Friday, April 04, 2014 2:33 PM
To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Antenna book

I'm sure this is some kind of heresy but I just have terrible time understanding the ARRL Antenna Book. Can you guys suggest something different that I can read that will help me understand antennas? I know that I am supposed to have a complete understanding of the subject to have a General Class license but that just ain't the case.

Thanks,

Jim, K6JMG

From: Bill Blomgren (kk4qdz)
Topic: 31890 Message: 31914

Fan dipoles need some 'spread' between the elements. I've got one up that starts off at "the connection" --- the 40 meter is the "top" element, then 20 is about 1 -2 feet down.. then the 10 meter element another foot below that. It's an inverted V optimized for the 20 meter world. (It's a bit off, impedance wise on 40 and on 10... 10 is a bit less than 90 degrees between the elements.. 10 is dead on.. 40 is a tad wide by 15-20 degrees. In an ideal world, they would start in the middle, and go straight out with the spacing constant.

Unfortunately, I live in an apartment with a VERY small space for the antenna It's a "shrunken 40" - so subopimal performance there.. works at best OK... Does great from 20 on up, however. (Worked Scotland on 10 meters 2 days ago.. FM on 10 watts... Thank goodness the KX3 has a great tuner!)

KK4QDZ - Now with Extra Class Priv's, and a tiny KX3 to enjoy them!

From: Bill Blomgren (kk4qdz)
Topic: 31890 Message: 31915

Good.. that one has a lot more plans in it. The big problem: details left out on some of the plans.

I'm building a 20 meter 'c" (folded dipole) --- it's 40" side to side. Something like 17 feet tall, with a gap on one side (waiting for the hamfest in 2 weeks to get some insulators for that part...) -- so 2 spreaders, one connector.. some "plain" insulated wire..and a choke to keep common mode out of the house...

It looks like a big C, and is ground indepenent. (sort of like the mag loops)

For verticals, a simply J pole or slim jim. makes a good VHF antenna. (2 meters, 440)

Which band are you looking at needing an antenna for?

Hello Gents;

I think that was on the 5 wire flat rotor cable – I knew a fellow that did that once long ago – he didn’t like it very well and in the end he cut it in half and tied it to the base of his multiband vertical – Not sure how that worked either, Hi – 73 Dave / WØDR

Here is what one fell did.

http://www.hamuniverse.com/n4jte6bandribbon.html
http://www.hamuniverse.com/n4jte6bandribbon.html

I imagine that the antenna can be loaded, with or without a tuner, but what its pattern looks like might require some analysis by someone with modeling skills.

31923. Re: [ham-antennas] ARRL Antenna Book

Yahoo group: ham-antennas (2014)
Date: 2014-04-05 08:16:50 UTC
From: Todd F. Carney / K7TFC
Topic: 31902 Message: 31923

You know, if you just Google "ham antenna basics" you'll find lots of fabulous stuff for free and definitely written at beginner levels. Here's an example:

http://www.hamuniverse.com/n4jaantennabook.html

I love books, but I also love Google and the very useful stuff people put online.

31924. RE: [ham-antennas] Antenna book

Yahoo group: ham-antennas (2014)
Date: 2014-04-05 12:25:45 UTC
From: Richard Schmuke
Topic: 31890 Message: 31924

Alex and Jim, I have never tried it that close. I have seen sketches of the idea but never in real life. I do know you cannot start with the highest frequency (10 or 6M), lower frequency first. My spacing was about 2” between the wires. There is a lot of interaction so start with the 160 or 80 first. The longest can be by the book and you increase in frequency the wire will need to be longer than the book. You can start and adjust at a low level then adjust for best SWR for each band and raise it when done.

http://s1102.photobucket.com/user/KD0ZZ/media/DSC00947.jpg.html

I used 14ga copperweld for the 80M wire and regular copper for the rest, spacers are split PVC conduit. It has held up thru several ice storms and owners, (I gave it to a friend). If you work up a flat ribbon cable one let us know how it turns out. I tried a multiband cone vertical and because of the varying capacitance of the wire in a cone shape it did not work. I now use a delta loop with a homemade balun for most bands. Back on books, I make my own book. If I want to know about a J-Pole , Slim Jim or baluns I Google several articles, print then out , put them in a binder then build it and try it.

http://s1102.photobucket.com/user/KD0ZZ/media/Book2.jpg.html

Rich, Kd0zz

I seem to remember an article about using rotor wire to make a multi band dipole. Might work.

Rich,

what happens to a fan dipole like you have if the individual wires are very very close to one another? I have a role of 8 conduction flat wire that I have been thinking about cutting individual wire are ever increasing lengths starting at about 10m but not fan them out.

James "Jim" M. Geidl, K6JMG
D.B. Cooper, you have a message.

Jim, the ARRL antenna book can be a little heavy reading at times. I have no electrical background but I like to build things. Once I make something I don't forget it. Start with a simple dipole, then a 2M vertical, different wire antennas are simple, a few scrap parts and you can put together a gama matched 2M beam. I made all of these before I even bought a analyzer. I build most of my antennas and baluns. Hands on helps me more. Just do a Google search on KD0ZZ and you will see several of my hits and misses in Photobucket. My 5 band dipole was a great hit, the 5 band vertical a complete miss.

I'm sure this is some kind of heresy but I just have terrible time understanding the ARRL Antenna Book. Can you guys suggest something different that I can read that will help me understand antennas? I know that I am supposed to have a complete understanding of the subject to have a General Class license but that just ain't the case.

Thanks,

Jim, K6JMG

From: Keith Heimbold
Topic: 31890 Message: 31925

Off topic from the fan dipole is a couple antennas that are fairly simple and require just a little soldering.

This one was pretty easy to make and was basically just follow the instructions.

http://www.iw5edi.com/wp-content/uploads/2012/12/InvertedL-160-80-40mG0CSK.pdf

The only thing I recommend is having an antenna analyzer to trim Wire lengths. It worked pretty well overall and would give you the lower bands. I eventually moved to quarter wave slopers for 80 & 160 and a k9ay receive antenna but that trapped inverted L got me initially on low bands for not a lot of effort.

Good luck!

Just echoing what everyone else has been saying. Decided to get up today and see if I could hear it. Sure enough. Nice and strong. Seems to be the loudest on 28.850 here in NW Ohio. Can hear it on most modes and is pretty wide signal. Can hear it in varying degrees going down to around 28.800 ish and up to around 29.000 or so. Also seems to come and go in intensity on the different frequencies at different times. Will likely keep an eye it.

As a citizen of Pennsylvania, you can get privileges at any Penn State University library, branch or main. This works great for journals and so on. Similar deals may apply in other states. You might be able to view journals and so on *online*, once you have a card. You might find you can access non-PSU online collections, too. You can search nationwide, too.

A research library is a wonderful thing. Research librarians are great people.

> Give your local librarians an opportunity to show you what they can do.

I have had mixed experiences with small libraries, but it's worth a shot. Be prepared to wait weeks. (USPS). Penn State, I believe, satisfies in-system ILL nearly overnight. I think they have their own couriers.

Rich,
What size is your delta loop? Is the Balun 4:1?

I guess you feed it with coax and then a tuner in the shack? Sounds appealing as a multiband antenna...

Rich,

What size is your delta loop? Is the Balun 4:1?

I guess you feed it with coax and then a tuner in the shack? Sounds appealing as a multiband antenna...

Best regards - Bry Carling AF4K

Brian , my loop was installed as a 80M size loop because of my small back yard, I am thinking about a 160 size but will have to run it thru some trees. I have enough property just too many trees. I trimmed it to a low SWR in the middle of the 20M phone band, with a 4:1 Guanella current balun at the feed point. The antenna needs a touch with a tuner for 17M , 80M and 30M. I don’t normally use it on 80 because I have a 160/80 fan dipole fed with 450 LL. Below is a chart from my book showing how one delta loop can work several bands. It has good gain on the higher bands. When you look at 10M you have as much wire as 16 regular dipoles and when resonate it works fine.

1X loop is a 100 Ohm antenna , a 2X loop and larger close to 200 Ohm

2X in length loop, or greater can be matched with 50 Ohm coax and a 4:1 Balun if

the overall length of the loop is a multiple of the length at that frequency

Even Multipliers will make it a resonate antenna, A 4X and 8X loop will match

the most bands when used with a 4:1 Balun

With the correct resonate length of the antenna no tuner adjustment is needed

on the 7 bands shown

31937. Re: [ham-antennas] Antenna book

Yahoo group: ham-antennas (2014)
Date: 2014-04-05 18:41:53 UTC
From: Alex Netherton
Topic: 31890 Message: 31937

I have a dipole I built out of a sheet of Plexiglas of about 3x8 or something like that. I made a strip of 10 ga wire along each edge, with a tiny loop for connection for 20, 17, 15, 12, 10 and 6. I spaced the loops about an inch apart, and soldered the corresponding bands on them, letting them swing, tying them to the wire above with carpenter's twine. Stretched between two trees, and made sure the wires did not touch or cross, and started tuning by checking each band at the bottom and top of each band, and tuning accordingly. 20 meters is 1.2:1, but some of the others got messed up from wind, and I need to work on them.

A good way to do it is to take a small mobile rig (I have an Icom IC-7000), get in a car with the mobile rig, lower the antenna to your reach, start tuning. When finished, put the feedline into the shack. Or, use an antenna analyzer (I don't have one).

From: <k9jfk@...>
Topic: 31890 Message: 31938

HI Jim...
Antennas are an acquired taste. Once you know the basics it is not necessary to know everything about the subject... that would take a lifetime. There are some good "general" books that will you start down a good path about technical subjects; produced by the government for training our military people, many are in the public domain and online.

For the Marine Antenna Handbook
http://www.zerobeat.net/r3403c.pdf http://www.zerobeat.net/r3403c.pdf

There are other books online, but that one will give you a good foundation without asking you to break new frontiers in physics.

yes I tried the opposite sideband and switched to AM and FM and tuned around to see if it was on a slightly different frequency . nothing changed so I am thinking it may be a new digital signal like Dstar or something . not have any experience with digital I have no idea if it can even be heard on a FT950 . would not think so but I have been fooled before .

From: <email4utoo@...>
Topic: 31951 Message: 31951

Howdy, looking for wire antenna designs that are light weight to put in my Backpack, (keep laughing i am 61 with larger pants than i want to share , or maybe they are big enough to share ! lol,hihi) , Ok going to run my 3-5watts output into it, on 80-10, but even single banders will be good, or ones i can plug together . Next i need designs for 200watts , i am planning to build a SState linear amp for boosting if needed , and i do not want to get of topic but if you have any good ideas on that , would also be appreciated. Yes you can recommend articles or books you know have what i need for this application. I thank you for taking time to help me in my Back to Ham Radio Pursuits , after 40yrs ! 73s and 2s , AJ KF5zYB OZARKS

I presume you'd prefer not to carry an ATU (although a QRP ATU doesn't weigh a whole lot). The "EFT-10/20/40 Trail-Friendly" from LNR is pretty convenient.

Personally, I use the EARCHI 20m EHFW for 20 meters (hung vertically). I use the same radiator for 40m, and replace the matching transformer with a BNC-to-binding post adapter and add 1 or 2 radials. It takes about 1 minute to switch from 20m to 40m, and most of that is the huffing and puffing I do to stand up and sit back down.

I do have an ATU, so I use a 33' wire, hung vertically for everything when operating backpack-portable. On 20m, I add the EARCHI matchbox for an EFHW. On 40m, I add radials and lose the matchbox for a 40m vertical. On 17m or 30m, I drive it as a non-resonant end-fed, and let the ATU sort it out. It is adequate to reach Washington (state) and Finland using SSB from north Georgia (but the other guys are doing the heavy lifting, with excellent beams).

Some people like to hang such a wire from the trees. I use a carbon fiber fishing pole, which I can guy in about 10 minutes, or bungee to a tree stump in a few less. I tried hanging it. Sometimes I could do it in 5 minutes; other times it took a half hour or longer. I decided that I wanted something I could count on. CF poles are available from AllFishingBuys. Yeah, carbon is somewhat conductive. I can't tell a difference between signal reports using carbon vs fiberglass, and CF is much lighter.

Whether or not you intend to participate in SOTA (I do), the nasota (North American SOTA) mailing list is full of people who do *lots* of backpack-portable QRP. End-fed or a dipole (possibly a linked dipole) seem to be the most popular HF antennas there.

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com] On Behalf Of Richard Schmuke
Sent: Saturday, April 05, 2014 5:26 AM
To: ham-antennas@yahoogroups.com
Subject: RE: [ham-antennas] Antenna book

Alex and Jim, I have never tried it that close. I have seen sketches of the idea but never in real life. I do know you cannot start with the highest frequency (10 or 6M), lower frequency first. My spacing was about 2" between the wires. There is a lot of interaction so start with the 160 or 80 first. The longest can be by the book and you increase in frequency the wire will need to be longer than the book. You can start and adjust at a low level then adjust for best SWR for each band and raise it when done.

http://s1102.photobucket.com/user/KD0ZZ/media/DSC00947.jpg.html

I used 14ga copperweld for the 80M wire and regular copper for the rest, spacers are split PVC conduit. It has held up thru several ice storms and owners, (I gave it to a friend). If you work up a flat ribbon cable one let us know how it turns out. I tried a multiband cone vertical and because of the varying capacitance of the wire in a cone shape it did not work. I now use a delta loop with a homemade balun for most bands. Back on books, I make my own book. If I want to know about a J-Pole , Slim Jim or baluns I Google several articles, print then out , put them in a binder then build it and try it.

http://s1102.photobucket.com/user/KD0ZZ/media/Book2.jpg.html

Rich, Kd0zz

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com] On Behalf Of Alex Netherton

I seem to remember an article about using rotor wire to make a multi band dipole. Might work.

Rich,

what happens to a fan dipole like you have if the individual wires are very very close to one another? I have a role of 8 conduction flat wire that I have been thinking about cutting individual wire are ever increasing lengths starting at about 10m but not fan them out.

James "Jim" M. Geidl, K6JMG

Jim, the ARRL antenna book can be a little heavy reading at times. I have no electrical background but I like to build things. Once I make something I don't forget it. Start with a simple dipole, then a 2M vertical, different wire antennas are simple, a few scrap parts and you can put together a gama matched 2M beam. I made all of these before I even bought a analyzer. I build most of my antennas and baluns. Hands on helps me more. Just do a Google search on KD0ZZ and you will see several of my hits and misses in Photobucket. My 5 band dipole was a great hit, the 5 band vertical a complete miss.

HI Jim...
Antennas are an acquired taste. Once you know the basics it is not necessary to know everything about the subject... that would take a lifetime. There are some good "general" books that will you start down a good path about technical subjects; produced by the government for training our military people, many are in the public domain and online.

For the Marine Antenna Handbook
http://www.zerobeat.net/r3403c.pdf

There are other books online, but that one will give you a good foundation without asking you to break new frontiers in physics.

From: Alex Netherton
Topic: 31951 Message: 31960

You can make a dipole with mini-coax such as RG-174 and use 20 ga wire, just be careful of such fine wire tangling. A dipole can be made for each band you are going to work, and they will only weigh a few ounces. Dipole length can be figured with the old formula of 234/f in mhz. For each leg, 123/f in mhz. I am sure you have made them in the past, but many SOTA types use dipoles such as this. I might use a RCA connector as the old Heathkits did, and put an adapter on the back of the radio and make the antennas even lighter.

Some use a wire and a tuner, but to each his own.

My comment had nothing to do with the fact that there was in fact an email that stated information about the beacon. Nor the fact that you had read it and others had not (myself included.)

My statement was only directed at the way that it was answered, unlike your other reply without the snappy comment because it was much more civil than "What part of this don't you get?"

73
Terry
P.S. I didn't misunderstand anything! It was ALL in the delivery!

Bill...

So are we. (Interested in antennas)

The topic *is* getting a bit long...but, it is already winding down and will soon die....as long as someone doesn't come on and try and enforce their wishes/values on the group.

Best thing you can do is learn to use your delete key or skip any topic that doesn't interest you.

If you are a moderator here, then make sure you sign that fact. so that we know your 'request' is from management.

And while you are at it, Bill, in any ham group, it is just plain courteous, to **always** sign with your call sign, if not seen in your FROM heading.

Good day sir!

Joe - W7RKN

My comment had nothing to do with the fact that there was in fact an email that stated information about the beacon. Nor the fact that you had read it and others had not (myself included.)

My statement was only directed at the way that it was answered, unlike your other reply without the snappy comment because it was much more civil than "What part of this don't you

get?"

Subject: Re: [ham-antennas] Need Ideas and solid info for SOTA or Camp type light weight Antennas

You can make a dipole with mini-coax such as RG-174 and use 20 ga wire, just be careful of such fine wire tangling. A dipole can be made for each band you are going to work, and they will only weigh a few ounces. Dipole length can be figured with the old formula of 234/f in mhz. For each leg, 123/f in mhz. I am sure you have made them in the past, but many SOTA types use dipoles such as this. I might use a RCA connector as the old Heathkits did, and put an adapter on the back of the radio and make the antennas even lighter.

Some use a wire and a tuner, but to each his own.

31966. Antenna feed lines

Yahoo group: ham-antennas (2014)
Date: 2014-04-07 10:07:21 UTC
From: KB3YRC
Topic: 31966 Message: 31966

I ran LMR -400 and some RG 213 from the terminal block from my shack to the
block in the attic.

And from the attic block out and up the tower to the antenna.

Those cables are cut to length and neatly mounted.

roughly totally less than 100 FT Each.

Do they need to be cut or lengthen to a % of the weave length .

Richard

Richard, they only have to be from the radio to the antenna. Length comes into play for matching assemblies and coax transformers. For normal antenna set up you are perfect. Good cable also, I can't understand people who use RG-58.

And yet another Richard , Kd0zz

yes I tried the opposite sideband and switched to AM and FM and tuned around to see if it was on a slightly different frequency . nothing changed so I am thinking it may be a new digital signal like Dstar or something . not have any experience with digital I have no idea if it can even be heard on a FT950 . would not think so but I have been fooled before .

Mel , and all , Thanks, will read all , now Mel , can you please explain, on your Data Graph , at top it had a ,"In Shack" column , with a 1.5 SWR at 3.5mhz, as example-- now , At Shack is what specifically What , with regard to length ? or did you use the antenna tuner ?(hey Mel,) it is probably not your Graph, but just the way i learn, maybe i am a little dyslexic, who knows, just needed some clarification so be wordy so i will get all i can, Thank You Mel and others !-- for taking the time to put these up - this is very very helpful to us Old Novices that come back to Amateur Radio , and younger ones !
by the way i just finished a emtech Zmatch tuner kit that is small and light and will Schlepp along , i will not worry about it's weight , but space is always a consideration as well , but it is small enough -besides , i stepped up and bought a huge NOS ,(new old Stock) Kelty 5900 Back Pack, this will give me incentive to go ,and get the exercise ! (yes and activations hihi). I was a big time hiker in the 50s-80s, Sota stuff and Genrally having fun camping will contribute to my good health- i hope hihi. After my first trip and will write here a short review of my antenna i use and how it worked , i do not have an Antenna tester yet, but will try to borrow one , them seem to be expensive, maybe you guys can recommend a kit or design for me that is light , Thanks, for all, AJ Hillbilly Ham-Ozarks, KF5ZYB 73s and 2s

my fan dipole has 40, 30, 20, 17 wires and covers 15, 12 and 10 with less
than 3 to 1 swr. The LDG 100 pro tunes all bands. I separated the wires
with 1/2 inch pvc about 4 footlong, so each wire is 12 inches separation.
With 1 : 1 W2AU balun at feed point it matches well to RG8X and required
minor adjustment of 40 to cover 15. Works very well.

Fan dipoles work best and tune best when not only the wires are separated, but also the feed points as well. It's a more complex build, but worth the effort and small extra cost. Mine has wires for 80, 40, 20 &10 and tunes 15 on the harmonic of 40. 80M is also quite wide banded. You can tune all bands with a tuner, except for 160M of course.

I made a 3 band fan . tried it with the wires parallel and it did not tune . separated them by 2 feet and it tuned .

Subject: Re: [ham-antennas] Antenna book

my fan dipole has 40, 30, 20, 17 wires and covers 15, 12 and 10 with less than 3 to 1 swr. The LDG 100 pro tunes all bands. I separated the wires with 1/2 inch pvc about 4 footlong, so each wire is 12 inches separation. With 1 : 1 W2AU balun at feed point it matches well to RG8X and required minor adjustment of 40 to cover 15. Works very well.

I like your "feeder." I realize that fans are separated. What I am fiddling with is having everything more or less in none jacket. This is more a case of having the wire and maybe making an antenna than needing the antennas and going out to get the wire.

Fan dipoles work best and tune best when not only the wires are separated, but also the feed points as well. It's a more complex build, but worth the effort and small extra cost. Mine has wires for 80, 40, 20 &10 and tunes 15 on the harmonic of 40. 80M is also quite wide banded. You can tune all bands with a tuner, except for 160M of course.

Messages in this topic

Which one do I go to for the files?
or do I have to start all over by going to yahoo groups and then look up ham antennas and does it then give us a link to the files section?

seems like there should be a link sombody can give us or put in the body of the posts.
they did give us a link, but error keeps coming up everytime i try to use it.
there must be a better way.
anybody have any ideas?
I am sure there are many others that have problems getting to these files too.

thanks for any help you can give this old man.

You can make a dipole with mini-coax such as RG-174 and use 20 ga wire, just be careful of such fine wire tangling. A dipole can be made for each band you are going to work, and they will only weigh a few ounces. Dipole length can be figured with the old formula of 234/f in mhz. For each leg, 123/f in mhz. I am sure you have made them in the past, but many SOTA types use dipoles such as this. I might use a RCA connector as the old Heathkits did, and put an adapter on the back of the radio and make the antennas even lighter.

Some use a wire and a tuner, but to each his own.

Hello,

I have on of these from North Huron Communications. Very light weight. Collapses down to 16 inches or so... Here is the YouTube video. Can find them on eBay. Reasonable price.

I've made Contacts from 1 to 100 watts on mine. Used it portable, backpacking, and just in the yard. I did make 3 additional radials for it. Talked to Hawaii, Russia, England. Etc. good signal reports. And it's all on a camera tripod.....

http://youtu.be/-PZN7InAUug

Hope this helps

I know it on all of the emails I get.
It is different on each group though, but it is there is some form or
another.

i read some eham reviews the other day, it seems the Alpha is built in the USA and seems better built, i know some like the Alex, if you go to a Hamfest or Store with both then you can see them up front and decide which is best for you , me i would buy the Alpha , cause i am a Patriot type . Best of Luck and let us know what and how it goes, i will be saving up for mine as well. AJ KF5ZYB

31998. Open Line

Yahoo group: ham-antennas (2014)
Date: 2014-04-09 18:02:22 UTC
From: Joe
Topic: 31998 Message: 31998
Attachments: 1 described; binary payloads are missing from this source WARC

I have always been a fan of open line antennas.

I'm shortly going to be putting a large "Sky Loop" up again and of course feed it via some open line.

BUT heres a question.

I will even be making the open line also. so i can make it any impedance i want to.

Now the question is,

300 Ohm TV twin lead, the lossiest (due to a lot of dialectric? or just the closer spacing? or both?)

the 450 ohm "Window Line" Less loss. (More "AIR" as the dialectric I assume, but how about the wider spacing?)

Actual 600 ohm open line where it is 99% air just some small spacers as needed to maintain the spacing. Least loss due to mostly air? or also the spacing.

Now is there any reason to stop at 600 ohm?

why not 800 or 1000?

I'm guessing there is an upper limit because the spacings would get far too wide, mechanically and possibly the self shielding aspect if it is too wide in termes of wavelength/

what would be the loss difference if went higher than 600 ohms? worthwhile?

Like i said I'll be homebrewing the feed to so can make it any impedance I want.

Yes. The wider the spacing, the lower the upper limit of frequency it can be
used for without incurring too much loss from radiation from the feedline.

Dialectic mostly, wire size secondly, spacing not really
>
> the 450 ohm "Window Line" Less loss. (More "AIR" as the dialectric

Spacing is not really a factor
>

Mostly Air.. also easier to actually maintain the spacing (or variations
due variations in spacing at the wider widths.
>
> Now is there any reason to stop at 600 ohm?
>
> why not 800 or 1000?

The wider the spacing the more apt the line is to radiate (and/ pick
up signals ..reciprocity)

>

Not IMO
>

> impedance I want.

Have fun..past experience taught me maintaining spacing is the tricky
part. One trick I have used in the past was to "stretch" the wire so as
to make it really straight, removing any memory it might have . I used
to tie one end off to the very base of the tower and then hook the far
end up to a garden tractor and pull the wire you can actually feel it

lengthen. if stretched properly it wont try to curl when released.

Radiation from the feed-line is NOT loss, it is however signal going
places that is likely not as beneficial as it were when reaching the
intended antenna (but not always :-))

But where does this happen? and at what spacings? and how does the losses happen too with the wider spacings? Even thos the 600 ohm is practically lossless as it is now. But hey if can get some more why not ya know? or is 600 the more or less upper limit and thats why it was the standard in the old days.

32003. AW: [ham-antennas] Open Line

Yahoo group: ham-antennas (2014)
Date: 2014-04-09 18:52:09 UTC
From: siegfried jackstien
Topic: 31998 Message: 32003

I would not go too high in the impedance ... reason is the line will radiate somewhat (more spacing gives more loss from radiation especially on the higher bands)

Next reason is ... if you have a very high impedance line you also can have very high impedance at the shack end (a lot higher if it is an odd multiples of a quarterwave)

Say you have a 80m loop fed at 20m ... impedance is not 100 nor 200 ohms ... say it is around 300 ohms (just guessing here) ... now a transforming line (odd multiple) could transform that way higher if also the line has a high impedance (high voltage ... arcing in the tuner etc.)

Mid impedance line gives also mid impedance at the shack end

....

What I do here is

I feed my topband loop with a quarterwave line on 80 (a bit lower as the 20m but also loop is a bit bigger to have the resonance in mid 80m band)

On topband I add another 20m (so also a quarterwave line on that band)

At the shack end a homebrewed 1:9 balun

Explanation of that setup:

On the lower bands (160 and 80) the impedance of the loop is low ... transforming that to around 400-500 ohms with the ladderline and then back down to 50 ohms with the balun ... tuner only needed at the band edges

From 40m and up the impedance of the loop is higher and so no transforming needed (line is matched) and that impedance also at the shack end is around 400-500 ohms ... after the balun then the impedance also is around 50 ohms

Even if the impedance would drop to 300 ohms or 350 ... that would be 30-40 ohms after balun ... swr around 1:1.5 or so ... (no ... not exact ... only calculation over the thumb ... grin)

...

On the higher bands a matched line (or almost matched ... that slight mismatch is no problem)

And on the lower bands a transforming line (added length switched in with banana plugs)

With making the loop a bit bigger and making the line shorter the resonance spots on the lower bands were the same ... but changed a bit on the higher bands ... and with that setup I have all bands below 1:3 (most are well below 1:2 and on some sweet spots exactly 1:1)

A real multiband antenna

I am sure with a higher impedance line I would have higher impedance at the shack end and loosing that multiband solution ... go figure

...

If anybody thinks those open wire feeders do not radiate, they are mistaken. Self shielding is great in theory. For me I will always use car wax after my bad experiences with open wire feeders and letter line.

One part for a rolling clock for each answer :-)

(just kidding)

Wider spacing gives radiation loss (and noise pick-up)

Dave
In my case it appeared as RF in the shack. It happens any time I try parallel feeders and rarely happens with coax. I have read all the reasons why parallel feeders are better and I don't buy it. I have mine away and will only use coax.

Best regards - Bry Carling, AF4K

From: Jim Bennett
Topic: 31998 Message: 32007

Hey Bry,

I had RF in the shack once in a while when I put up my antenna, but is is resolved, and it was pretty easy. I run about six feet of RG-8X coax from the back of my KPA500 amp and KAT500 tuner to an MFJ window-passthru. From there about eight feet of RG-8X to an under-eve Balun Designs 4:1 balun, then 110 feet of commercially made 450 ohm ladder line to my doublet. It is 88 feet long and about 45 feet high. The KAT500 finds a great match on 60-6 meters, as does the internal tuner on my K3, if I'm not using the amp and the matching tuner. No RFI problems in the shack. To be doubly certain, I passed a couple of my serial-->USB cables through mix 31 donuts a couple times.

I also run this same antenna tuner & amp configuration from my KX3, driving the amp to about 250 watts with 12 out from the KX3. Neither the 250 watts from KX3 or 500 from K3 cause me any grief from RF. :-)

Then you ARE doing something wrong for sure. I ran legal Limit with
oopen line ALL the time on ALL bands, and not the tuner to coax till it
gets out side either, I brought the open line right into the shack it
passed litterally less than a foot from everything in the shack and
never ever had a problem.

Gotta think in terms of a wavelength at the frequency of interest...The higher the frequency the more likely the line is to radiate for a given spacing..

One trick to reduce the radiation effect is to twist the line..but again the higher the frequency the tighter the twist required to the point that you reach a point of impossibility ..at HF (below 50Mhz) this is typically not a the issue

Bry

Not sure what the car wax does but if you got RF burns from an open wire line or RF in the shack this is more likely about voltage nodes (wavelength of the feedline) and poor ground RF grounds in the shack than it is about the line actually radiating RF

You can always make open wire co-ax. I've seen it used at a MW broadcast facility, 100kw. Four outer wires with an inner wire. The spacers were quite wide apart and the outer wires about 4 to 6 inch apart. It was taken out of service when some kids found that throwing bits of wire at it produced a good display.

I've also seem, at SW broadcast site open wire lines spaced with 1/4 wave stubs. All constructed out of about 1 inch (presumably) tubing.

Cheers
Will

32014. Alpha Delta Sloper vs. end fed longwire, thoughts?

Yahoo group: ham-antennas (2014)
Date: 2014-04-10 13:14:10 UTC
From: <ve3tmt@...>
Topic: 32014 Message: 32014

Hi group,

I'm currently using an Alpha Delta DX-B sloper for the low bands, 30m and below. The top of the sloper is about 30' in the air going down to about 10' at the low end. Performance isn't bad, but I like to get a little more local coverage on 75m. I'm also unable to achieve anything lower than a 3:1 SWR on this band as well.

Looking at the idea of running an end-fed longwire off the tower instead. At the low end I could add another 30' feet or so of wire and tie it off in a tree, making the overall length approximately 90'. The antenna would look like a half square with the center lower than the ends.

Looking for input on this, is it going to be worth the effort? I can only run one antenna off the tower, so it's the sloper or this. Is a 9:1 balun the right choice to feed it? Will the radiation pattern be skewed by using this configuration? I am very limited in the way I can set this up.

Thanks,
Max
VE3TMT

I build my own vertical weighs less than 5lbs, telescopes out up to 31 feet and uses a lightweight balun with 4 12 foot radials. With a tuner it covers 160-6 without a problem. Everyone I have had try it winds up keeping them.

Very low noise and easily put up and/or taken down. Have used them in all conditions with out guying and tested them from mountains, beaches, mobile home parks, etc. Best vertical I have ever used and I have tested everything from Gap through MFJ, as well as S-9, and the rest of what is now being sold. The only antennas that work as well as these are Zero-5 antennas and they are portable.

Thanks for considering my post.

I have an Alpha-Delta DX-CC 5-band on 3 wires with coils on the 40M for 80.
Alpha-Delta separates each set of wires by about 3"
using their special UV-resistant PVC. It has no balun built in. I'm getting
S5 to S9 reports, although I think the S9 is just folks being nice.

My MFJ-962D tunes the SWR down to 1.1:1 or better.
The meter on the 962D shows PEP around 60W, driven by a TS590-S at 100W.

If I separated the wires and ran each set into it's own 1:1 balun and coax
feedline, would I expect to see better FWD power?

I realize 60W is pretty good but I'm not breaking the pile the way some
100W stations appear to do. Of course they also typically have Yagis or
Quads that they can get a lot more concentrated signal directivity.

Tnx, 73s
Steve K0HAY

32029. Re: Fan dipole;

Yahoo group: ham-antennas (2014)

From: <w8alphadelta@...>
Topic: 32028 Message: 32029

Hi Steve, the spacing between the wires is enough for peak operation. It is designed to give maximum performance as it is. It is designed to be used without a balun. More than likely, the installation site may not be ideal. The antenna, or any HF antenna for that matter, is designed to be operated "in the clear", at least 35 ft. or more in height above ground and at least 20 ft. from any roof tops, gutters or surrounding metal objects.

Since the 962 tuner tunes it down to a low SWR, I don't think anything else would improve the performance unless you changed the installation. The key is, what is the feed point SWR without the tuner? If it is high, then look for improvements in the installation site to get an improvement in the signal.

As it is, in comparing signals to those with beams and such, the performance is probably close to optimum.

73,

Don, W8AD, Alpha Delta

Steve, in addition to what Don said, you did not state height of antenna, length of feedline, type of feedline, etc.
Long runs of rg58 will eat up the watts. High SWR will also increase the loss.
3db will drop power from 100 to 50 watts, 2 db to about 65 to 70 watts,
The meter on the MFJ may be out of calibration, reading off due to the mismatch or you have something wrong in your setup that is causing you to lose power before it goes up the feedline. You stated the power reading on the "matchbox" was 65 watts. That is not the power into the antenna. Which means you may be losing receiving signal level also.
Take a good review of your setup, integrity of connectors and coax and both elimination of current on the outside of the coax shield and good grounding - RF grounding not just AC/DC ground.

Steve

1)Approximately how long is your feed-line?
2)What is the SWR on each band WITHOUT the tuner?

Generally speaking you will unlikely see much if any improvement by
using a separate feed-lines for each band

ON 20-10M even a modest 2 element beam at 30-40' will typically be
better than your alpha delta by a couple of S-units which is enough to
step on you on a pile up

I think too much is often made of losing "half your power" due to line loss, SWR loss, etc.Half your power or double it, it is only 3 dB, which is only a half an S unit. 65 watts is plenty. I cracked a pileup the other night with only 10 watts - I had forgotten to turn the power back up after tuning up - and got a 5x9. Being kind, sure, but I got in there.
I am using about 40 feet of rg-58, into a fan dipole, or a ladder line into a 102 foor center fed flattop. They both work fine.

Cracking a pileup with 60 or 100 watts is not going to be much difference on the DX end; they will sound essentially the same. A good antenna will make a difference, but don't go out and drop a bunch of money on a Rohn tower, a Tailtwister rotor (do they still make those?) and a Mosley 5 element multiband beam (is Mosley still in business?). Here you are talking in the 4 to 5 figure hit to the checkbook. And honestly, running a beam at 100 feet with an old FT-101 or TS-520 with leaky caps and muddy receive is not going to bring you much joy.

I part with people who say to put your money into antennas. I say get the best rig you can afford, make the best antenna you can make, and have fun. I think a $800 or so rig for a newcomer, like a FT-857D, a FT-450, or if you can afford it, a FT dx1200. I know Yaesus best, but Kenwood and Icom make similar rigs at a similar price point. With this, you can experiment with antennas and when you can afford it, get or make a directional antenna. The rig will have digital signal processing, (probably), and a whole host of other things (mine actually has digital noise reduction) that make working a station easy and fun, and the finest antenna in the world is not going to do that.

I would suggest working on your antenna some, and read the "DX Code of Conduct". Lots of DX stations will not answer if they think you are not operating "up to snuff"

Also, if your rig supports it, use audio processing. One of my rigs has a speech compressor, a speech processor, and other speech enhancement (so does the other, but it is hidden in menus), and flipping that on can add enough to my voice that I am heard in a pileup only after I turn it on. Warning: do NOT use it in ragchews, roundtables or nets. Your voice punching out of somebody's speaker will get you a contact in a pileup, but is most unpleasant when sitting around talking.

Good luck and good DX

Steve

I am rookie in this hobby I purchased a used 33 Ft tower and beam antenna and rotter 30 years old, cleaned it up made some repairs. Ran an 80 meter dipole, Purchased a Yaesu FT857-D and was off to the races like the new kid on the block. Well I was disappointed talking to the others in my town I heir Japan I heir XXX. Well I don't and was disappointed. Thinking that I wanted to be like the big boys I purchased an 1KW amp. I thought I was big shit. Still not listing to the others around me at club meeting's and wasting money. What can those old buzzards' of 80 and 90 teach me. It took me two years to listen.

Well the amp is on the bench because of something stupid I did, and yes the contesters will give you a 5/9 just to get rid of you and go to the next. But let me tell you Location, location, Location, Time, and Propagation, Propagation, Propagation.

The other week in a contest at 8 AM on a Sunday morning I made my longest contact of 10,000 miles bare foot. (no amp)

Go to 3.990 at 5:30 - 6 AM-7 AM and listen, I learned I am just as good as the big boys at 100 Watts

Enjoy the hobby

Richard

In the past 35 years I have learned that working DX is a lot like fishing . Hearing a letter or two of a call counts as hearing some one and you can assume they heard a letter or two of your call . One could say you worked each other .....sort of like watching a large fish swim by your bait .....had he been hungry you could have caught him . This is " Horse Shoe " fishing or DXing & quite popular on street corners and club meetings . Remember , when you have the bonce , you have the bonce . On the other hand , I have five fingers . 32035. Power, antennas, and propagation

Yahoo group: ham-antennas (2014)
Date: 2014-04-12 15:34:03 UTC
From: <soona4sail@...>
Topic: 32035 Message: 32035

As we all know, the antenna is a very important part of any amateur radio station. That includes the radiator(s), the feedline, and any parts in between, including the ground. For those of you experiencing frustration about lack of space for antennas, or budget concerns, or neighbourhood restrictions, take heart. It was gratifying last night, to be involved with the ANZA net, and listen to Australian Foundation licences (max power 10 watts) and a QRP station (5 watts) working stations in western Canada, and the Eastern USA.(Conneticut) The signal reports were outstanding, The QRP station was on a beach with an 11 ft vertical, and two of the 10 watt stations had dipoles at less than 20 ft height. This was on 15 mtrs, at 0415 Zulu, well into the evening on the west coast. So, simple antennas, well designed, can work wonders, especially if the propagation is in your favour. Good DX Hope this gives the frustrated members of the group some hope. 73 John

Yup.

Just to see how difficult it would be to do, I've worked 35 countries, most of them on 40 meters, with a crystal-controlled military transmitter, a T-784 (part of the AN/GRC-109), running a maximum of 15 watts input, to an end-fed, low, "long wire".

It was fairly easy, and was GREAT fun. Apparently, a weak signal is easier for some DX stations to pick out of a pileup than all the loud ones...at least that is what I have been told.

The last DX I worked with that transmitter, I was also using the R-1004 receiver. This was also on 40 meters a few months back.

Well said John

After moving to a new QTH late October, 2011 before the onset of winter, I put up my trusty backup antenna (Butterntut HFV-9) and a modest set of elevated radials. Running 100watts I worked DXCC in 26 days, granted CQWW CW Contest helped make a lot of stuff available in a short window but it further validates your point about relatively simple antennas and modest power.

Dave,
Your meter is showing the power being offered based on voice peaks. Transmitting a continuous or CW (key down) signal, the meter will show the maximum amount of output power. An SSB signal is only about 40% to 60% of your CW output.

If you aren't hearing DX stations as well as others, it may be more of a function of the antennas direction. Try and compare received signals with the other members of the club and you will be able to better judge your antenna system.

73,
John K0EBC

Ten or twenty years ago three local OT's use to get on the local 2
meter repeater and compare signals of stations in eastern Europe that
they were working for hours on end, starting after dark, they were
mostly using the then current (HF packet, clover etc.) digital modes,
learning the ends and outs, no one else listening to them on the
repeater bothered them, other than for a quick sked, everyone enjoyed
hearing it all. Those were some swell guys, all three /SK by now.

The league is based on cooperation and it isn't dead, yet.

Thanks to all responders for some very good information on my Alpha Delta DX-CC.

On some things I left out:

the DX-CC is up about 25ft at the center, in a tree hung from a branch about 2ft away from the trunk.
The segments or legs go out pretty much flattop but with a little droop to tie-off points at about the same 25ft above ground.
There is no metal withing 100ft of the antenna at any point.
The ground slopes at about 35deg with the antenna running parallel to the slope (not up/down slope).
The slope puts the ground at the upper end about the same 25ft from the antenna but maybe a little closer, more like 20ft.

The feedline is 100ft of RG8X from feedpoint to a ground rod where it attaches to a static burst gas-tube protector clamped
to the ground rod. From the other side of the protector, a run of 50ft of RG8X leads into the shack and to the radio which is
a Kenwood TS-590S. All connections on the feedline are taped with Scotch Super-88 and Coax-Seal (that gummy stuff).

SWR values from MFJ-259B analyzer attached in the shack to the antenna cable:

(freq, Reactance, Inductance, SWR)

40M=
7040, 57, 3, 1.1 (low SWR point)
7175, 31, 7, 1.6
7185, 30, 7, 1.6
7195, 29, 6, 1.7
7200, 29, 5, 1.7
7220, 27, 5, 1.9
7240, 25, 7, 2.0
7260, 24, 8, 2.1
7280, 23, 10, 2.2
7300, 22, 12, 2.4

20M=
13915, 56, 15, 1.3 (low SWR point)
14225, 54, 43, 2.2
14250, 49, 44, 2.2
14275, 45, 44, 2.3
14300, 42, 43, 2.3
14325, 37, 42, 2.4
14350, 35, 42, 2.5

15M=
20400, 30, 0, 1.6 (low SWR point)
21275, 44, 47, 2.5
21300, 47, 49, 2.5
21325, 49, 50, 2.5
21350, 53, 52, 2.5
21375, 56, 53, 2.6
21400, 60, 54, 2.6
21425, 64, 56, 2.6
21450, 69, 57, 2.6

Values with MFJ-259B attached via 18ft cable to feedpoint of DX-CC:

40M=
7049, 52, 6, 1.1 (low SWR point)
7175, 61, 27, 1.6
7200, 54, 36, 1.9
7240, 44, 45, 2.3
7280, 34, 48, 2.7
7300, 30, 49, 2.9

20M=
13830, 44, 13, 1.3 (low SWR point)
14225, 14, 16, 3.6
14275, 13, 17, 4.0
14350, 11, 19, 4.4

As a check, I put a Vectronix dummy-load at the antenna-end of that 150ft of RG8X with a Daiwa CN-801 inline (after the Xcvr) and ran TX-TUNE:

Xcvr output W, Daiwa Fwd W, (SWR=1:1 all cases)
10, 9.5
50, 40
75, 60
100, 85

I think the bottom line is that the cable length is where most of the loss is occurring but I could get better performance by raising the antenna and maybe moving it to a location over level ground and higher than 25ft.

Would LMX-600 help with the cable? What about level ground and height above ground?

Thanks again to everyone who had the perseverance to read through all this! Special thanks to Rich KB3YRC, Alex KC4BO, Dave NR1DX, Don W4BWS and Don W8AD.

Hi Steve,

The SWR numbers are OK and can easily be handled by a wide range antenna tuner. However, there is evidence of some coupling to the earth ground causing the low SWR points to be low in frequency. If you could raise the antenna and use a larger coax like LMR400 or RG8 type, you would eliminate some loss caused by that long run of RG8X. With the higher antenna and larger 50 ohm coax I think you'd have an improved signal.
73,

Don, W8AD

Well, if you are not hearing people that others in your area are, I would do some antenna work. I got back into the hobby/service last May, and having some money ahead (first time in this life, *sigh*), I went whole hog, bought a Yaesu FT-950, a power supply, a LDG AT-100ProII automatic antenna tuner, and just because I could, bought a MFJ-1777 antenna and a balun to hook into the tuner.

My first few contacts, almost a year ago, include: Dominican Republic, Venezuela, Asiatic Russia, Bulgaria, Puerto Rico, and Estonia. That is in the first week. 100 watts on a wire. Last week was similar. Though I have no tower, and no beam, and (up until a few weeks ago) no amplifier. I like to flip the amp on and smell the warm tubes, look at the pattern the light from the cathode heaters makes on the ceiling, and on a cold Spring evening, it warms up the room. I don't use it often, and have only used it once for DX.

It is indeed location and conditions, but a center fed wire can do a lot. Get it as high as you can, orient it in the direction you want to work, and get happy.

I suspect your getting more than 60w pep. If that meter does not use a battery or 12v power it will not give proper pep readings.

35' is probably ok for 10 thru 20. On 40 and 75 it will have a high angle of radiation at 35' which is generally ok for stateside.

All your swr "sweet spots" are at the lower end if not outside of the band(s) ... I would fold backs a few inches at the ends and then measure again

(yes a tuner can handle that ... but without a tuner needed you would get rid od the additional tuner loss

If you put the wattmeter next to the dummy load you'll get a real perspective of what loss you have, it's really a eye opener.

"Why this SPAM ??????"

Because people's computers get compromised by virii/trojan horses/whatever.

Or their email accounts get hacked or otherwise compromised.

It happens. Just ignore it. Don't spread it by including the whole text
including the URL that you DO NOT WANT TO GO TO.

Andy

>>Why this SPAM ??????

Why not?

Actually, many people are getting their accounts hacked on Yahell, and maybe more since the Heartbleed bug has been discovered. The reasons are multifold:
1. Insecure passwords. People use simple passwords that are easily guessed.
2. Bad or no security on free mail servers. AOL, Yahoo, Hotmail, etc, and once someone hacks them, and you lose them, you can never get them back.
3. Poverty and/or greed in Lower Slobbovia. Truly, many of the former Soviet Empire... sorry, I mean Union (my Socialist friends will understand that I do NOT consider the former Soviet Union "Socialist" or even "Communist", as it is difficult to have a Democracy in an Authoritarian Totalitarian state). Once the Soviet Union fell, the former Union and satellite states began to look for ways to make $$. Hacking into computers and generating SPAM is one way, since a SPAM URL that generates a spambot<http://en.wikipedia.org/wiki/Spambot> every
time a virus is passed on makes a lot of money, and if the URL steals financial info from each computer infected, that is just more money into Croatia, Serbia, Albania, or whatever state you might care to name. Most of these states have little or no Internet fraud laws, and the money pumped into their state coffers is appreciated. It is just business.
4. Some people love to make others miserable, and stealing accounts is just one way to do it.

Don W8AD, Rich KB3YRC, Alex NR1DX and others,

Thanks again for all the input, I now have a plan and we'll see where that takes me.

1. replace the RG8X by LMR400
2. raise the antenna to at least 40ft AG

Item 2 above will also require moving it over level ground, getting it further away from ground
coupling.

Now I just have to work on the XYL-acceptance-factor, hihi (or Har-de-Har-Har as Ralph Cramden
would say).

Steve - do what I did 14 years ago - have the XYL get a ham ticket. She will at least understand what you are trying to do and might be more sympathetic! :-)

She got her 13 wpm General ticket not long after arriving here from the Philippines on a fiancee visa. Now is KF6ZNT. Trust me, it helps!!!

Don't forget the XYL about the safety factor , by raising it higher you reduce the RF radiation effect on the rabbits and lost tortoise making it better for nature and the environment J

OK, thanks sigi, I can do that at the outer ends of the 20 and the 10 wires on the DX-CC
but the 40M wire has coils at the ends to take it to 80M so I'll have to look at that.

I'll try moving and raising it first and then touch up the lengths after that.

Don W8AD, what do you think about this idea?

32059. Weatherproofing coax connectors

Yahoo group: ham-antennas (2014)
Date: 2014-04-14 22:36:37 UTC
From: <barkowskitim@...>
Topic: 32059 Message: 32059

Hello,
I have a few questions regarding weatherproofing coax antenna connections. I'm a new ham and have just spent the winter building antennas. I have a VHF, UHF, a long wire, a 20m dipole and soon a multiband Hi-Gain vertical ready to put into service at my QTH. Spring has sprung and it's time to get them into the environment. In addition I have several other antennas on the plan book as well….Yeah, I like trying out new antennas.
I live on the SW British Columbia coast. It rains here…..a lot….like 7-8 months per year. In the past as I SWL, I had sealed my coax connection with Coax-Seal type tape as my weatherproofing material. It worked fine but removing it was always a pain in the butt. I've got some for this installation but I have also purchased some internal connector sealant called "S.T.U.F." for Silicone Teflon Unionizing Filler. (http://www.crossdevices.com/cross_devices_004.htm http://www.crossdevices.com/cross_devices_004.htm) and Silicone sealing tape (http://www.qsradio.com/Coax%20and%20ladder%20line.htm http://www.qsradio.com/Coax%20and%20ladder%20line.htm) as a possible "neater" alternative. I was wondering if any of you have used this combination with PL-259 and N connectors in the HF, VHF and UHF frequency ranges and what problems and successes you have encountered.

Thanks and 73,

Tim

Hard to beat Coax-Seal actually. I use electrical tape on the connector first, and then the Seal. A utility knife splitting the weathered joint down the road enables the stuf to peal away rather nicely and usually clean.

The "STUF" if teflon and silicon means the connector possibly cannot be resoldered. I have had problems soldering to surfaces that have seen silicon. I use black Scotch 33 tape and then coaxseal or ductseal over the tape, keeps weather out for long time.

The thing is to keep the connectors clean, Teflon tape that’s a new one for me, we used black electrical tape and roll it on backwards sticky side out. then rubber and a covering of scotch 33 or 66. Then when you cut it off it peels off.

32066. Pattern for my Trap L

Yahoo group: ham-antennas (2014)
Date: 2014-04-15 06:17:24 UTC
From: <rolandbrade@...>
Topic: 32066 Message: 32066

I have a HF9V but it is a bit short for working DX on 160.
I decided to make a Trap L as I only have a small back garden.
I wonder if someone could put it through their antenna program so that I can see the radiation pattern.
At the moment it has a 32 foot vertical with a 40 metre trap attached and then comes out horizontally for 22 foot to the 80 metre trap. The last leg is 40 foot. I was hoping this would be shorter. The last 15 foot of this last leg comes down as I don't have enough room to get it in.
Obviously my 80 metre trap needs a bit more L and less C on it.
In my initial tests it is at least on a par with the Butternut but eventually I intend to get the vertical leg up to somewhere around 45 foot or so.
Many thanks chaps
Roley G3VIR

Rob, if you are referring to the thin Teflon pipe thread tape then Coax Seal over the top of it, that is a great idea and lets you have a clean removal when you disassemble.

I've got some for this installation but I have also purchased some internal connector sealant called "S.T.U.F." for Silicone Teflon Unionizing Filler. (<http://www.crossdevices.com/cross_devices_004.htm> http://www.crossdevices.com/cross_devices_004.htm) and Silicone sealing tape (<http://www.qsradio.com/Coax%20and%20ladder%20line.htm> http://www.qsradio.com/Coax%20and%20ladder%20line.htm) as a possible "neater" alternative.

I was wondering if any of you have used this combination with PL-259 and N connectors in the HF, VHF and UHF frequency ranges and what problems and successes you have encountered.

Thanks and 73,

Tim

Tim,

I know the goo problem to which you refer too well. I got away from coax seal about 5ish years ago. What I now use is self-fusing silicone tape. It can be purchased from any home improvement store (I get mine at Menards) or electrical supply house. It leaves ZERO residue, as it isn't sticky at all. It only sticks to itself. And it is completely UV resistant. You just have to be careful to stretch it tight enough, but not too tight. It also covers irregular shapes pretty well.

It costs a bit more than electrical tape or coax seal, but when you need to remove it, you'll find it to be PRICELESS. You just slice it carefully with a sharp knife and it pops right off.

Subject: [ham-antennas] Weatherproofing coax connectors

Hello,

I have a few questions regarding weatherproofing coax antenna connections. I’m a new ham and have just spent the winter building antennas. I have a VHF, UHF, a long wire, a 20m dipole and soon a multiband Hi-Gain vertical ready to put into service at my QTH. Spring has sprung and it’s time to get them into the environment. In addition I have several other antennas on the plan book as well….Yeah, I like trying out new antennas.

I live on the SW British Columbia coast. It rains here…..a lot….like 7-8 months per year. In the past as I SWL, I had sealed my coax connection with Coax-Seal type tape as my weatherproofing material. It worked fine but removing it was always a pain in the butt. I’ve got some for this installation but I have also purchased some internal connector sealant called “S.T.U.F.” for Silicone Teflon Unionizing Filler. (
<http://www.crossdevices.com/cross_devices_004.htm>
http://www.crossdevices.com/cross_devices_004.htm) and Silicone sealing tape (
<http://www.qsradio.com/Coax%20and%20ladder%20line.htm>
http://www.qsradio.com/Coax%20and%20ladder%20line.htm) as a possible “neater” alternative.

I was wondering if any of you have used this combination with PL-259 and N connectors in the HF, VHF and UHF frequency ranges and what problems and successes you have encountered.

Thanks and 73,

Tim

Roley,

It can be done and I know it has been done, but...

The problem is mechanical strength of the top of the antenna (J section) to support the trap, the wire weight and handle the stress of the guy lines that will be required.

Subject: [ham-antennas] Pattern for my Trap L

I have a HF9V but it is a bit short for working DX on 160.

I decided to make a Trap L as I only have a small back garden.

I wonder if someone could put it through their antenna program so that I can see the radiation pattern.

At the moment it has a 32 foot vertical with a 40 metre trap attached and then comes out horizontally for 22 foot to the 80 metre trap. The last leg is 40 foot. I was hoping this would be shorter. The last 15 foot of this last leg comes down as I don't have enough room to get it in.

Obviously my 80 metre trap needs a bit more L and less C on it.

In my initial tests it is at least on a par with the Butternut but eventually I intend to get the vertical leg up to somewhere around 45 foot or so.

Many thanks chaps

Hi Tim,
I use STUF on all my connectors for both HF and VHF/UHF. It keeps air pockets out of the union which prevents moisture ingress. Never had a problem, and all my connectors are soldered and crimped.
As for the tape, I use Coax Wrap sold by RF Parts and many others. It is a silicone tape that only sticks to itself and will release from the cable and connectors with no sticky residue. No sticky on my hands after handling Coax Wrap either.
I have never had a sealed connection fail using the STUF in conjunction with the Coax Wrap, and I live in a very wet area with huge temperature swings. I do use a heat gun and heat the Coax Wrap after I have sealed the union, that speeds the cure. Just do not heat it over 350 degrees F for curing. It will cure on its own too, but since I lay my coax on the ground before I hoist it in the air, I did not want the stuff to be slightly sticky and pick up fir needles and grass clippings, and heating solves that issue.
I have never attempted or needed to ever re-solder a connector once sealed, but suspect a good solvent cleaning would remove any remaining STUF, it is not particularly sticky just about the consistency of kid's play clay. But, I would never reuse a connector after soldering either because of the heat required to pull the center connector bond.

Scott,
An interesting note. Thank you.

In a quick search online I see a number of suppliers with little information as to the quality offered or where it is manufactured. I try to avoid cheap overseas products in this kind of an application.
Have you found a preferred brand?
What kind of life have you experienced outside in the sun?

Not on the threads, at least I wouldn't. Point was waterproofing the connection. Electrically, I wouldn't do anything that might disturb good electron flow.

As I said, I made the swap about 5 years ago. But in 5 years, it shows little to no degradation.

My preference is the rescue tape brand, which is a little thicker and is sold at most hamfests. But if I run out, I go to Menards to get the big roll of it. I have no idea where any of it is made.

Replace the Electrical tape with Rescue tape... When you cut it, it
actually jumps off the connector! :)

Hi, I found the best to weatherproof antenna connections is to us Self Amalgamating Tape it is tape that is not sticky but it stretches and is a rubber so it holds onto it self I have had it in the air for at least 5 years with no dramas what so ever, here in Australia we can get it at JCar or any good electrical hardware outlet, I hope this has been of help to the group, Cheers 73's John vk4ylu.

Is there any reason not to try to get 12 & 17 on a 10,15,20 fan dipole?

You don't see warc bands on commercial models so I wander if there is excessive interaction or some other reason. I'd like to try my hand at a rotatable fan dipole.

Attachments: 1 described; binary payloads are missing from this source WARC

What I have done since the 60's is,

I will wrap it with a good high quality electrical tape. Like 3M etc. Applying it with a 50% stretch as wrapping (50% stretch is stretching it almost twice as long as it's resting state length)

I apply one spiral layer.

Then I spray it with any good quality outdoor spray paint.

When th paint is almost dry. It's still tacky tho. I again wrap it again with another tight spiral layer of the tape wrapping it in the other direction.

Then spray it again with the paint.

Then when tacky apply another tape layer.

then one last coat of paint.

I have opened connections like this 20 years old and they are as shiny as they were the day it was sealed.

I have 12 and 17 meters on my fan dipole. I made mine to run 40, 20, 17, 12, and ten. If really had no problems with interaction. I did have a little hi swr when I first tuned it. But figured out why I did. All I needed to do was put alittle more space between the other legs. I average . 2.0 to 1.1 swr. I use a LDG tuner and have a 100ft of coax from the shack...

My original spacing was 3in(7.6cm) between each leg. I changed it to 4 1/2in(11.4cm) and it worked well. Spreaders are PVC drilled just larger than the 12 ga stranded wire I'm using.

Other than a minor change or two. I'm impressed with my first homebrew antenna. It's only about 20ft(3.6m) off the ground. I'm only running barefoot(100watts) or lower

I second the use of self amalgamating tape. It stands the high U.V. in ZL and is definitely water proof/resistant. Comes off cleanly.

Cheers
